Flame Atomic Absorption Spectrometry

Analytical Methods
Safety Notices

CAUTION

A CAUTION notice denotes a hazard. It calls attention to an operating procedure, practice, or the like that, if not correctly performed or adhered to, could result in damage to the product or loss of important data. Do not proceed beyond a CAUTION notice until the indicated conditions are fully understood and met.

WARNING

A WARNING notice denotes a hazard. It calls attention to an operating procedure, practice, or the like that, if not correctly performed or adhered to, could result in personal injury or death. Do not proceed beyond a WARNING notice until the indicated conditions are fully understood and met.
Important Warning

WARNING Eye, Explosion and Hearing Hazard

Aspiration of perchloric acid and perchlorates into a nitrous oxide-acetylene flame can create an explosion hazard, which can result in death or serious personal injury including temporary or permanent impairment of hearing. Do not use perchloric acid unless it is absolutely essential for sample preparation. If perchloric acid must be used, it may be possible to reduce the risk of an explosion by taking the following measures:

- Use an air-acetylene flame instead of a nitrous oxide-acetylene flame.
- Reduce the concentrations of perchloric acid and metal in all analytical solutions to the lowest practical level. The concentration of perchloric acid should be reduced in the digestion stage and further reduced by extending the fuming stage.
- Aspirate all solutions for the shortest practical period.
- Always aspirate distilled water between samples. Minimize the aspiration of air.
- Use separate spray chamber/liquid trap assemblies for perchloric acid analyses and organic solvent analyses to prevent perchloric acid from mixing with organic solvent residues.

NOTE

When solvent extractions of perchloric acid solution are performed, some of the acid may dissolve in the organic solvent that is subsequently aspirated. In addition, if the organic solution is aspirated whilst floating on the surface of the acid, do not allow the capillary tube to drop below the organic solvent and suck up aqueous perchloric acid.

- Clean the burner frequently — never allow the burner to clog, and wash it thoroughly both inside and out.
- Minimize the amount of acetone which is carried over with the acetylene by:
  - ‘Cracking’ the bottle before use by gently opening the valve to check for any drops or spray of acetone. Any bottle showing acetone should be returned to the supplier for replacement.
  - Storing and using the bottles in the vertical position.
  - Using only one instrument per bottle.
  - Using only ‘instrument’ grade acetylene.
  - Replacing bottles when the pressure drops to 750 kPa (100 psi).
- Ensure that all safety covers are in position, and wear approved ear protectors and safety glasses.
- Ensure the pressure relief bung of the spray chamber can be easily removed by hand. Refit the bung according to the operation manual.

1. Introduction

General

This book is intended as a guide to analysts in the selection of techniques and instrument settings for practical flame spectroscopy. Although the techniques and settings quoted will give satisfactory results for the majority of determinations, it is impossible in the space of this book to provide for all contingencies. Consequently, where analytical circumstances differ appreciably from those indicated in the book, appropriate changes in operating conditions may be required.

Throughout the book, emphasis had been placed on practical applications and no attempt has been made to provide a complete theoretical background. Readers seeking a more thorough theoretical treatment of the subject are referred to the many text books currently available — see ‘General References’ later in this section.

Also, while every effort has been made to ensure the validity of the published material in this book, analysts should satisfy themselves that the written procedures and operating conditions, (and the results obtained from these) are valid.

Safety Aspects

Some warning messages will appear in the text. These are used when failure to observe instructions or precautions could result in injury or death.

Note, however, that many chemicals used in the preparation of samples and standards in this text are potentially hazardous. If you are in any doubt over the correct handling procedures for any material, you should consult an appropriate reference on the subject.

You should also observe the warning on Page 3 of this book, and refer to Reference 8 (at the end of this section).

Other points to note are:

- A flame should never be left unsupervised.
- Buildup of salt or carbon deposits on a burner should never be allowed to continue unchecked.

Refer also to Agilent instrument operation manuals for details of required safety practices.
Reagents and Apparatus

The purity of reagents may determine the accuracy of the analysis and all reagents should therefore be of the highest purity available.

Prior to any analysis all reagents and equipment should first be checked for the element of interest by carrying out a blank determination.

All apparatus for trace analysis should be thoroughly soaked in dilute nitric acid and rinsed several times with distilled water prior to use. It is recommended that a full set of new apparatus be put aside expressly for use in trace analysis, thus minimizing any possibility of contamination.

PTFE and plastic volumetric vessels are available and should be used in preference to glass whenever hydrofluoric acid or strong caustic solutions are to be handled.

Sample Preparation

The sample to be analyzed can be brought into solution by a number of means:

- acid attack
- alkali fusion and subsequent acid attack
- dissolution in solvent

Whichever procedure is used, it is essential to ensure that no analyte element is lost and that a clear, stable solution is obtained.

When carrying out dissolution it is advisable to avoid adding components likely to cause severe interference. For example, in the alkali fusion of tantalum ores, potassium should not be used since it will form highly refractory potassium fluorotantalate.

Where interferences are severe, or the concentration being determined is very low, chemical separation or pre-concentration may be necessary. In atomic absorption analysis this is generally achieved by solvent extraction.

Solvent extraction can also be used to remove a major element and reduce the overall solution concentration. In iron and steel analysis, ketone or ester extraction from strong hydrochloric acid solution removes iron almost quantitatively, and trace elements can be determined in the aqueous layer. This eases the requirements for matrix matching of standards.

When choosing a solvent for organic extraction, avoid using aromatics such as benzene, or highly volatile halogen solvents such as carbon tetrachloride and chloroform. Apart from their hazardous nature, these types of solvent will create severe flame disturbance.

The ketone and ester solvents have been found to possess the most suitable properties for use in premix burner systems. Methyl isobutyl ketone, diisobutyl ketone and ethyl acetate are the solvents most commonly used because of the wide range of metals which can be chelated and extracted with a high degree of efficiency.

Detailed methods for solvent extraction of metals can be found in the literature.

When working with any aqueous-organic system it is good practice to subject the standards to the same extraction procedure as the samples. This automatically compensates for the slight solubility of solvents in water, the extraction efficiency involved (which is rarely 100%), and any metallic impurities in the solvent.

Standard Preparation

Stock solutions for atomic absorption spectrometry (as 1000 μg/mL) are readily available for a wide range of elements from commercial suppliers. Alternatively, standards may be prepared from the solid.

Wherever possible, metals and metal oxides are to be preferred in the preparation of standards. This enables the analyst to dissolve them so that samples and standards will contain identical elements and hence minimize any chemical or physical interference effects.

Only concentrated standards (above 1000 μg/mL) should be held in storage. Working standards should be diluted from standard stock solutions only when needed.
At low concentrations (less than $10\ \mu\text{g/mL}$) solutions have been found to deteriorate quite quickly because of adsorption on the walls of the container.

Similarly, standard addition solutions can be prepared containing all of the required elements. This will avoid multiple splitting of the sample for individual elements and reduce the amount of time spent in preparing standards.

Before weighing, standard materials should be treated to ensure that they are in a standard state.

**Metals**

Wash with acetone and ether to remove any oil layers. Remove any oxide coating by abrasion with emery cloth or by acid pickling and drying.

**Oxides**

Dry at 110 °C for two hours. If necessary, heat to elevated temperatures to remove bound water.

**Compounds**

Equilibration at constant water content, or drying at 110 °C for two hours to remove any water.

For more detailed information the reader is advised to consult the many texts on classical chemical analysis.

**Matrix Effects**

**Precipitation**

Inaccurate results are commonly caused by precipitation of the element of interest. Examples of this are: the hydrolysis of silicon and tin compounds, and the formation of insoluble chlorides and sulfates.

**Physical Properties of Standard and Sample**

For a given flow of support gas, the amount of sample aspirated by the nebulizer and the proportion which reaches the flame are dependent on the physical properties of the solution — viscosity, surface tension, density, solvent vapor pressure. To avoid differences in the amount of sample and standard which reach the flame, it is necessary that the physical properties of sample and standard be matched as closely as possible. If this cannot be done, the method of standard additions must be employed.

**Chemical Interferences**

The formation of ground state atoms can be inhibited by two general forms of chemical interferences. These are:

- Incomplete dissociation of compounds
- Ionization

**Incomplete Dissociation of Compounds**

The most common form of this interference is the formation in the flame of such refractory compounds as calcium phosphate and potassium fluorotantalate. Such interferents form compounds which are not completely dissociated at the temperature of the flame and hence prevent the formation of neutral ground state atoms.

When establishing an analytical technique, use the following method to check for chemical interference:

1. Prepare a set of solutions of varying interferent levels.
2. Take absorbance readings for each solution.
3. Plot the results as shown.
Introduction

It will be noted that in region B, small variations in interferent level will cause large changes in the absorbance of the analyte element. Because this is analytically undesirable, the analyst should use a sample treatment procedure which will avoid operating in region B.

Where interference is encountered, the following procedure for optimization of the flame stoichiometry is recommended:

1. Prepare two calibration standards having the same analyte element concentration – one being prepared in distilled water and the other in a synthetic matrix corresponding to the sample material.

2. Light the flame and measure the absorbance of both solutions. Adjust the burner position for maximum absorbance with the synthetic matrix solution, and adjust the fuel flow until the absorbance of both solutions is identical, or as close as possible.

This procedure will provide optimum flame stoichiometry and minimize the effects of interference to yield improved accuracy and precision.

If interference is still present and cannot be compensated for, then 4 means of overcoming it are possible:

Use a Higher Temperature Flame

Where compounds are insufficiently dissociated in the cooler flames, a high temperature flame such as nitrous oxide-acetylene can frequently supply sufficient thermal energy to cause complete dissociation. For example, calcium interference on aluminium can be overcome by using the nitrous oxide-acetylene flame to dissociate the refractory calcium aluminate found in cooler flames.

Extract the Analyte Element

Where the interference assumes serious proportions, it is sometimes possible to extract the analyte element into an organic medium. When choosing a chelating agent it is unnecessary to ensure high selectivity; it is only necessary to insure that the interferent and analyte are separated. For example, potassium interference on tantalum can be avoided by extracting tantalum as the fluoride complex into methyl isobutyl ketone, thus preventing the formation of refractory potassium fluorotantalate.

Extract the Interferent

It is often possible to remove the interferent by organically extracting it from solution. A highly specific and quantitative extraction is not always necessary. For example, in the determination of trace metals in iron ores, the excess iron can be extracted into isobutyl acetate as the chloride complex. This allows trace analysis to be carried out on the aqueous solution free of bulk iron.

Use of Releasing Agents

The formation of some refractory compounds can be prevented by adding an excess of another element which will combine with the interferent in preference to the analyte. This will remove the interference. For example, in calcium determinations, lanthanum or strontium nitrate can be added to solutions containing phosphorous. This will allow calcium to be determined in an air-acetylene flame without interference due to the formation of calcium phosphate.
Introduction

Ionization

High temperature flames such as nitrous oxide-acetylene may cause appreciable ionization of the analyte element. The alkali and alkaline-earth metals are more susceptible to ionization than the transition elements.

To control ionization of the analyte it is necessary to add a suitable cation having an ionization potential lower than that of the analyte. The addition of readily ionized elements such as sodium, potassium and cesium at concentrations between 2000 and 5000 μg/mL creates an excess of electrons in the flame and effectively suppresses ionization of the analyte.

When investigating ionization levels, it is recommended that a graph be plotted of suppressant concentration against analyte absorbance as shown.

From the graph a concentration of ionization suppressant should be chosen such that minor changes in suppressant concentration have no effect on the analyte absorbance.

Some typical ionization potentials are:

<table>
<thead>
<tr>
<th>Metal</th>
<th>Ionization Potential (eV)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Al</td>
<td>6.0</td>
</tr>
<tr>

</tr>
</tbody>
</table>

It should be noted that the degree of ionization will vary with the concentration of the analyte element. When using more concentrated solutions (as for example when operating on alternative wavelengths), ionization may not present a serious problem.

Nebulizers

The nebulizer and glass bead can be set to achieve the desired analytical performance dictated by your sample type. For example, they may be set to achieve a high absorbance signal, or to accommodate high dissolved solids sample solutions. Refer to the appropriate Agilent documentation for details. Organic solvents also have specific nebulizer requirements.

Organic Solvents

Adjustable Nebulizer

When an organic solvent is analyzed by flame atomic absorption spectrometry, it effectively contributes extra fuel to the flame. It is recommended that an adjustable nebulizer is used for aspiration of organic solvents, and that the uptake rate be limited to about 1–2 mL/min depending upon the solvent.

Spray Chamber

When organic solvents are used regularly, it is recommended that the organic solvent spray chamber assembly is used. Refer to the latest Agilent documentation for details.

Observe safety practices when using flammable organic solvents. Refer also to Agilent instrument operation manuals.
**Recommended Instrument Parameters**

**Working Conditions (Fixed)**

The conditions listed will provide optimum performance for dilute aqueous solutions.

If chemical interference is known to be present then it may be necessary to use the hotter nitrous oxide-acetylene flame in order to eliminate interferences and obtain optimum conditions for precision and accuracy.

With some elements, the flame stoichiometry can greatly affect the analytical signal. It is therefore desirable to examine the effect of flame conditions (or stoichiometry) on the signal. An oxidizing flame is one with low acetylene content, while a reducing flame has a relatively high acetylene content. Reducing flames become luminous due to the excess amount of carbon.

**Working Conditions (Variable)**

The upper limit of the working range concentration will give about 0.8 to 1.0 absorbance. The lower limit of the working range is about 10 times the defined detection limit. This range may be altered by burner rotation in order to avoid dilutions.

The alternative wavelengths shown have been selected to give a variety of working ranges. In some cases other analytical lines are available. However, the sensitivities are no better than the listed lines and the latter have been preferred because of the relatively better signal strength and spectral purity. The slit width indicates the spectral band width expressed in nanometers.

**Flame Emission**

| Wavelength | 396.1 nm |
| Slit width | 0.1 nm   |
| Fuel      | acetylene |
| Support   | nitrous oxide |
| Flame stoichiometry | reducing; red cone 1–2 cm high |
| Burner height | 5–8 mm |

*Note 1: Adjust for optimum performance.*

Aluminium emission appears in the center of a strongly emitting CN band in the flame. Major factors in the determination at low levels of detection are the adjustment of fuel-support ratio and burner height.

The use of flame emission is only recommended for very low concentrations of aluminium in solutions of simple aqueous matrix.

**Interferences**

Aluminium is partially ionized in the nitrous oxide-acetylene flame. To suppress ionization, add potassium nitrate or chloride to give final concentration of 2000 μg/mL potassium. The addition of a readily ionizable element such as potassium overcomes enhancement interference from other alkali metals.

Enhancement also occurs with the following elements:

<table>
<thead>
<tr>
<th>Element</th>
<th>Concentration Range (µg/mL)</th>
<th>%Enhancement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Co</td>
<td>50–5000</td>
<td>3–5</td>
</tr>
<tr>
<td>Fe</td>
<td>50–5000</td>
<td>4–15</td>
</tr>
<tr>
<td>Mn</td>
<td>50–5000</td>
<td>4–11</td>
</tr>

<td>Ni</td>
<td>50–5000</td>
<td>* -26</td>
</tr>
<tr>
<td>Ti</td>
<td>50–5000</td>
<td>8–14</td>
</tr>
</tbody>
</table>

* -2% at 50 μg/mL

These interferences are dependent on flame conditions and burner height\(^{1}\). A fuel rich flame (red cone 1.5–2 cm) decreases the effect.

Silicon depresses aluminium absorbance by the formation of an undissociated refractory complex\(^{2,3}\). Addition of lanthanum can minimize the effect of silicon, calcium and phosphate on aluminium.

Interference effects can be minimized by matching the sample and standard solutions with respect to the major matrix elements in the sample.

<td>1.0</td>
<td>10–350</td>
</tr>
</tbody>
</table>

**NOTE** The 189.0 nm wavelength is normally used only with an evacuated system because of atmospheric absorption.

**Vapor Generation Method**

At low concentrations, this element is best determined by the vapor generation technique. Details of the appropriate procedures are given in the operation manual supplied with the Agilent vapor generation accessory. See also Reference 6.

**Flame Emission**

Arsenic is not generally determined by flame emission because of the poor emission characteristics of the element.

**Interferences**

**Spectral Interference**

One of the main sources of interference in the determination of arsenic is the molecular absorption of flame gases and solution species at the extreme ultraviolet region of the spectrum where the most sensitive lines for arsenic occur (193.7 nm and 197.2 nm).

This non-atomic absorption can be corrected by means of a continuum light source such as a deuterium lamp.

Interferences

Few interferences have been noted in air-acetylene flames. However, large excesses of iron, copper and calcium have been found to suppress the result where gold is extracted into MIBK.

Solvent extraction techniques have been developed, which remove any interfering element.

Large quantities of noble metals such as platinum and palladium interfere with gold analysis. A 1% uranium solution has been used as a releasing agent for this interference. The nitrous oxide-acetylene flame will remove any interference but provides a lower sensitivity.

Support nitrous oxide

Generally a flame having a red cone 1 cm high with the burner 1–2 mm below the light path will be found to be nearly optimum.

Boron is not usually determined by flame emission because of the poor emission characteristics of the element.

Interferences

Sodium has been found to cause interference when the ratio of sodium to boron is very high. The effect is usually minimized by adjusting the flame to neutral stoichiometry (red cone 0.5–1 cm high) with consequent loss of sensitivity.
Ba (Barium)

A.W. 137.3

Preparation of Standard Solutions

Recommended Standard Materials

- Barium Carbonate A.R. Grade \( \text{BaCO}_3 \)
- Barium Chloride A.R. Grade \( \text{BaCl}_2\cdot2\text{H}_2\text{O} \)

Solution Technique

Dissolve 1.7785 g of \( \text{BaCl}_2\cdot2\text{H}_2\text{O} \) in water and dilute to 1 liter to give 1000 μg/mL Ba.

Recommended Instrument Parameters

Atomic Absorption

Working Conditions (Fixed)

- Lamp current: 20 mA
- Fuel: acetylene
- Support: nitrous oxide
- Flame stoichiometry: reducing; red cone 2–3 cm high

Working Conditions (Variable)

<table>
<thead>
<tr>
<th>Wavelength (nm)</th>
<th>Slit Width (nm)</th>
<th>Optimum Working Range (μg/mL)</th>

<td>0.5</td>
<td>0.2–50</td>
</tr>
<tr>
<td>350.1</td>
<td>0.5</td>
<td>120–24000</td>
</tr>
</tbody>
</table>

Flame Emission

- Wavelength: 553.6 nm
- Slit width: 0.1 nm
- Fuel: acetylene
- Support: nitrous oxide

Severe spectral interference will be observed when measuring barium in the presence of calcium due to a strong CaOH band occurring around the same wavelength.

Interferences

Barium is partially ionized in the nitrous oxide-acetylene flame. To suppress ionization, add potassium nitrate or chloride solution to give final concentration of 2000 μg/mL potassium in all solutions including the blank. The strong emission from barium falling on the photomultiplier may result in a considerable increase in shot noise evidenced by increasingly noisy signals as the concentration of barium increases.

Barium absorbance in an air-acetylene flame is severely depressed by phosphate, silicon and aluminium. This is overcome by the use of a nitrous oxide-acetylene flame.
Be (Beryllium)
A.W. 9.012

Preparation of Standard Solutions

Recommended Standard Materials
Beryllium metal strip or wire  99.99%
Beryllium oxide  99.99%

Solution Technique
Dissolve 1.000 g of beryllium metal in 20 mL of 1:1 sulfuric acid containing a trace of hydrochloric acid. Dilute to 1 liter to give 1000 μg/mL Be.

Recommended Instrument Parameters

Atomic Absorption
Working Conditions (Fixed)
Lamp current  5 mA
Fuel  acetylene
Support  nitrous oxide
Flame stoichiometry  reducing; red cone 1–2 cm

Working Conditions (Variable)
Wavelength (nm)  234.9
Slit width (nm)  1.0
Optimum working range (μg/mL) 0.01–4

Flame Emission
Wavelength  234.9 nm
Slit width  0.1 nm
Fuel  acetylene
Support  nitrous oxide

Interferences
Sodium and silicon at levels in excess of 1000 μg/mL have been found to severely depress beryllium absorbance.
Aluminium has been reported (1,2) to suppress the absorbance by 25%. This was overcome by the presence of 1.5 g/L of fluoride.

The use of a slightly more oxidizing flame and increased lamp current will improve signal stability.

**Flame Emission**

Wavelength 223.1 nm  
Slit width 0.1 nm  
Fuel acetylene  
Support nitrous oxide  

The use of flame emission for bismuth is not recommended because of the poor emission characteristics of the element.

**Interferences**

No chemical interference at levels up to 10000 $\mu$g/mL interferent has been reported for the determination of bismuth with an air-acetylene flame.

**Vapor Generation Method**

At low concentrations, this element is best determined by the vapor generation technique. Details of the appropriate procedures are given in the operation manual supplied with the Agilent vapor generation accessory and Reference 3.

</tbody>
</table>

Flame Emission

Wavelength 422.7 nm
Slit width 0.1 nm
Fuel acetylene
Support nitrous oxide

Maximum intensity is obtained with an oxidizing nitrous oxide-acetylene flame (red cone 1 mm high).

Interferences

Chemical interferences in the air-acetylene flame are pronounced and have been fairly well documented\(^{(1,2,3,4)}\). These interferences, which depress the calcium absorbance, can be eliminated by the introduction of a releasing agent such as strontium (5000 \( \mu \text{g/mL} \)) or lanthanum (10000 \( \mu \text{g/mL} \)). Normally the addition of a releasing agent is used in conjunction with the practice of matching sample and standard solutions to obviate combined interference effects.

The presence of excess sodium or potassium causes 5–10% signal enhancement due to suppression of ionization.

In the nitrous oxide-acetylene flame the main interference is caused by ionization of calcium itself. This is overcome by the addition of a more readily ionisable element such as potassium (2000–5000 \( \mu \text{g/mL} \)).

Flame Emission

Wavelength  425.4 nm
Slit width   0.1 nm
Fuel         acetylene
Support      nitrous oxide

Interferences
Cobalt, iron and nickel (particularly in the presence of perchloric acid) have been found to cause depression of chromium absorbance.

This can be overcome by the use of an oxidizing air-acetylene flame or preferably a nitrous oxide-acetylene flame. No ionization suppressant is necessary.

Several authors\(^1\,^2\,^3\) have found interference in air-acetylene flame from copper, barium, aluminium, magnesium and calcium. The extent of interference is strongly dependent on the flame stoichiometry. Optimization of the stoichiometry or the use of the nitrous oxide-acetylene flame can eliminate the interference.

Slit width 0.1 nm
Fuel acetylene
Support air

Interferences
Interference from citric acid has been reported\(^1\) to suppress the absorbance by up to 50% for a citric acid level of 200 µg/mL. The effect is not overcome by adjustment of flame stoichiometry.

The interference has been minimized by measuring the absorbance in the presence of phosphoric acid. It is necessary to select an optimum burner height to gain maximum freedom from interference.

There is also some evidence that high sulfate concentrations have a slightly depressive effect on iron determination.

The use of a nitrous oxide-acetylene flame has been found to remove all interference.

Ge (Germanium)
A.W. 72.59

Preparation of Standard Solutions

Recommended Standard Materials
Germanium metal granules or strip 99.9%

Solution Technique
To make 250 mL of 1000 ppm Ge:
1. Weigh 0.25 g germanium powder into a 100 mL beaker.
2. Add 5 mL water and 2 pellets (0.4 g) KOH. Swirl to dissolve, and then cover with a watch glass.
3. Add 5 mL 30% H2O2 dropwise, over several minutes. The mixture becomes warm and turns milky white.
4. After the initial reaction subsides, add 2 more KOH pellets and allow them to dissolve.
5. Break up any remaining lumps of unreacted Ge powder with a glass rod and heat on a hotplate.
6. When effervescing ceases, add water to make the volume up to 20 mL and boil until the solution is clear. Add water as required to keep the volume at 20 mL.
7. Cool, then transfer to a 250 mL volumetric flask containing about 50 mL water.
8. Add 25 mL concentrated hydrochloric acid and make up to volume. This gives 1000 ppm GE in roughly 1 M HCl.

Recommended Instrument Parameters

Atomic Absorption

Slit width 0.1 nm
Fuel acetylene
Support nitrous oxide

Interferences
No chemical interferences have been reported.

Note 2: Adjust carefully for optimum sensitivity by varying fuel flow.
**Hf (Hafnium)**

A.W. 178.5

**Preparation of Standard Solutions**

**Recommended Standard Materials**

Hafnium metal  99.9%

**Solution Technique**

Dissolve 1.000 g of hafnium metal strip in 5 mL hydrofluoric acid, 5 mL water by the slow DROPWISE addition of 10 mL of concentrated nitric acid. Allow the reaction to subside before each addition. Dilute to 1 liter to give 1000 μg/mL Hf.

**Recommended Instrument Parameters**

**Atomic Absorption**

**Working Conditions (Fixed)**

Lamp current  10 mA
Fuel  acetylene
Support  nitrous oxide
Flame stoichiometry  reducing; red cone 1–2 cm high

**Working Conditions (Variable)**

<table>

**Flame Emission**

Wavelength  368.2 nm
Slit width  0.1 nm
Fuel  acetylene
Support  nitrous oxide

Hafnium is usually determined by atomic absorption.

**Interferences**

Hafnium absorbance has been found to be suppressed by sulfuric acid, hydrofluoric acid, alkali metals and alkaline earth metals. Most transition group metals interfere. In many cases the interferents affect the absorbance when present in concentrations as small as 50 μg/mL, with hafnium at 100 μg/mL. The use of an oxidizing nitrous oxide-acetylene flame can minimize most of these effects. However, the development of analytical techniques where the interferent is usually present at minimal concentrations is recommended. Matrices of sample and standard solutions must be carefully matched.
Hg (Mercury)
A.W. 200.59

Preparation of Standard Solutions

Recommended Standard Materials

Mercury metal   99.99%
Mercuric Chloride A.R. Grade   HgCl₂

Solution Technique

Dissolve 1.354 g of mercuric chloride in 10 mL nitric acid. Dilute to 1 liter to give 1000 μg/mL Hg.

Recommended Instrument Parameters

Atomic Absorption

Working Conditions (Fixed)

Lamp current   4 mA
Fuel   acetylene
Support   air
Flame stoichiometry   oxidizing

Working Conditions (Variable)

Wavelength (nm)   253.7
Slit width (nm)   0.5
Optimum working range (μg/mL)   2–400

Vapor Generation Method

At low concentrations, this element can determined by the vapor generation technique. Details of the appropriate procedures are given in the operation manual supplied with the Agilent vapor generation accessory. Refer also to Reference 5.

Flame Emission

Wavelength   253.7 nm
Slit width   0.1 nm
Fuel   acetylene
Support   nitrous oxide

Mercury is not usually determined by flame emission.

Interferences

Mercury (I) and mercury (II) show different sensitivities in the air-acetylene flame.

Mercury (I) is more sensitive due to the disproportionation reaction.

\[ \text{Hg}^2+ \rightarrow \text{Hg}^2+ + \text{Hg}_0 \]

Elemental mercury is readily atomized with 100% efficiency.

The ‘cold vapor technique’ can be used for trace determinations of mercury\(^{(1,5)}\). Metallic ions which are reduced to the elemental state by stannous chloride can interfere with the cold vapor method. They can amalgamate or form stable compounds with mercury\(^{(2,3)}\).

With both flame and cold vapor techniques, it is advisable to check for the absence of non-atomic absorption.

Flame Emission

Wavelength 559.0 nm
Slit width 0.1 nm
Fuel acetylene
Support nitrous oxide

Below 25 μg/mL, determination by flame emission is preferred, although the wavelength required must be accurately isolated to avoid spectral interference from the other rare earth elements. At higher concentrations, atomic absorption is normally used.

Interferences

Holmium is partially ionized in the nitrous oxide-acetylene flame. To suppress ionization, add potassium nitrate or chloride solution to give a final concentration of 2000 μg/mL potassium in all solutions including the blank. Holmium absorbance has been found to be suppressed by hydrofluoric acid, aluminium and silicon.
In (Indium)
A.W. 114.8

Preparation of Standard Solutions

Recommended Standard Materials
Indium metal strip or wire 99.9%

Solution Technique
Dissolve 1.000 g of indium metal in a minimum volume of 1:1 nitric acid and dilute to 1 liter to give 1000 μg/mL In.

Recommended Instrument Parameters

Atomic Absorption

Working Conditions (Fixed)
Lamp current 5 mA
Fuel (Note 1) acetylene
Support air
Flame stoichiometry oxidizing

Note 1: Fuel flow must be adjusted carefully for optimum sensitivity and detection limit conditions.

Iridium is usually determined by atomic absorption.

Interferences

Chemical interference in the air-acetylene flame is extremely diverse(1). In simple solutions, the overall effect of a particular element is markedly dependent on the concentration ratio of iridium to interferent. In general, aluminium, copper, lead, platinum, sodium and potassium enhance the absorbance by over 50%; titanium, tin, nickel, iron and palladium tend to depress the signal by amounts greater than 30%. The interference pattern in the complex matrix of ores, minerals etc. is extremely difficult to categorize.

Fortunately, an empirical means of overcoming the major interference effects has been reported(2). Although (in common with many releasing agents) the chemistry of the reaction has not been investigated, it has been found that a copper-sodium mixture (7000 μg/mL Cu; 3000 μg/mL Na) is very effective in counteracting the interferences. The mixture is prepared from the sulfate salts of the respective elements. Copper nitrate, at a much higher level (20000 μg/mL Cu) has also been used to overcome these interferences(3).

The flame emission signal for lanthanum is quite intense. Determination by flame emission is therefore preferred, although the wavelength required must be accurately isolated to avoid spectral interference from the other rare earth elements.

Interferences

Lanthanum is partially ionized in the nitrous oxide-acetylene flame. To suppress ionization, add potassium nitrate or chloride solution to give a final concentration of 5000 μg/mL potassium in all solutions including the blank.

Both absorption and emission signals for lanthanum are depressed in the presence of phosphates, fluorides, silicon, aluminium and iron, and by other rare earths. Many solvent extraction procedures can be found in the literature; one simple method is extraction at pH 7 with 0.1 M cinnamic acid in hexane. Otherwise rigorous matching of sample and standard solutions is necessary to control interferences. No chemical releasing agent has been discovered.
Li (Lithium)
A.W. 6.939

Preparation of Standard Solutions

Recommended Standard Materials
Lithium carbonate Li₂CO₃ 99.9%

Solution Technique
Dissolve 5.324 g of Li₂CO₃ in a minimum volume of 1:5 nitric acid and dilute to 1 liter to give 1000 µg/mL Li.

Recommended Instrument Parameters

Atomic Absorption
Working Conditions (Fixed)
Lamp current 5 mA
Fuel acetylene
Support air
Flame stoichiometry oxidizing

Flame Emission

Wavelength 466.2 nm or 451.9 nm

Slit width 0.1 nm

Fuel acetylene

Support nitrous oxide

Note that the emission at 466.2 nm arises from the LuO band emission, while at 451.9 nm the emission is a line due to Lu atoms.

The flame emission signal for lutetium is quite intense. Below 400 µg/mL, determination by flame emission is preferred, although the wavelength required must be accurately isolated to avoid spectral interference from the other rare earth elements. At higher concentrations, atomic absorption is normally used.

Interferences

Lutetium is partially ionized in the nitrous oxide-acetylene flame. To suppress ionization, add potassium nitrate or chloride solution to give a final concentration of 2000 µg/mL potassium in all solutions including the blank.

Absorbance and emission signals are depressed in the presence of phosphates, fluorides, silicon, aluminium and iron, and the other rare earth elements. Non-specific solvent extraction methods are available to circumvent some of these interferences. No chemical releasing agents are known.

**Interferences**

Hydrofluoric acid increases the absorbance signal up to 2% HF, but greater concentrations depress the signal. Sodium in the presence of 2% HF depresses the signal. By analogy with zirconium it is expected that 0.1 M NH₄F would eliminate some of these interferences and enhance the signal, although data for Nb has not been published.

Niobium is appreciably ionized in the nitrous oxide-acetylene flame and it is therefore recommended to add about 0.1% potassium chloride as an ionization suppressant.

</tr>
<tr>
<td>362.5</td>
<td>0.5</td>
<td>100–8000</td>
</tr>
</tbody>
</table>

NOTE The 352.5 nm line is preferred because the calibration is less curved over the working range and the signal is less susceptible to non-atomic absorbance than at the more sensitive 232.0 nm line.

Flame Emission

Wavelength 341.5 nm
Slit width 0.1 nm
Fuel acetylene
Support nitrous oxide

Interferences
At 232.0 nm wavelength, non-atomic species in the flame absorb strongly. Where the sample has a high concentration of dissolved solids it is necessary to correct for non-atomic absorption by using the background corrector. At 352.5 nm, this effect is negligible even for high matrix solutions.

In hydrochloric and perchloric acid solution, a slight (5%) absorbance depression has been observed in the presence of iron, cobalt and chromium. In a more oxidizing flame the effects are minimized and in the nitrous oxide-acetylene flame no interferences are observed.
Os (Osmium)
A.W. 190.2

Preparation of Standard Solutions

Recommended Standard Materials
Osmium tetroxide OsO₄, resublimed

Solution Technique
Dissolve 1.340 g OsO₄ in 100 mL water with the addition of a sodium hydroxide pellet to assist dissolution. Dilute to 1 liter to give 1000 μg/mL Os.

NOTE Osmium solutions may not be very stable and standard solutions should be freshly prepared.

WARNING Toxic Hazard
Avoid handling osmium solutions or breathing osmium vapors as these are toxic.

Recommended Instrument Parameters

Atomic Absorption
Working Conditions (Fixed)
Lamp current 20 mA
Fuel acetylene
Support nitrous oxide
Flame stoichiometry reducing; red cone 1–2 cm

An air-acetylene flame can also be used but with poorer sensitivity.

Working Conditions (Variable)

P (Phosphorus)

A.W. 30.97

Preparation of Standard Solutions

Recommended Standard Materials

Ammonium dihydrogen orthophosphate 99.0–101.0%

Solution Technique

Dissolve 37.138 g of dried NH₄H₂PO₄ in water. Dilute to 1 liter to give 10000 μg/mL P.

Recommended Instrument Parameters

Atomic Absorption

Working Conditions (Fixed)

Lamp current 10 mA
Fuel acetylene
Support nitrous oxide
Flame stoichiometry reducing; red cone 1–2 cm

Working Conditions (Variable)

Wavelength (nm) 213.6
Slit width (nm) 1.0
Optimum working range (μg/mL) 400–30000

NOTE Better linearity is obtained with narrower slit widths. Signal to noise ratio is increased.

Flame Emission

This method is not recommended.

Interferences

The relative lack of sensitivity of phosphorus means that determination by flame atomic absorption spectrometry is not common and the literature contains few references. It is recommended that either an interference study be carried out or matrix-matched standards be used.

References

Pb (Lead)
A.W.207.19

Preparation of Standard Solutions

Recommended Standard Materials
Lead metal strip or wire 99.9%

Solution Technique
Dissolve 1.000 g of lead in 1:1 nitric acid.
Dilute to 1 liter to give 1000 $\mu$g/mL Pb.

Recommended Instrument Parameters

Atomic Absorption

Interferences

No cationic interferences have been reported for the air-acetylene flame, however a number of anionic interferences have been reported. Phosphate, carbonate, iodide, fluoride and acetate suppress lead absorbance significantly at concentrations ten times greater than lead. These interferences can be largely overcome by addition of EDTA solution so that the sample solutions are 0.1 molar with respect to EDTA.

At the 217.0 nm wavelength, non-atomic species in the flame absorb strongly. Where the sample has a high concentration of dissolved solids it is necessary to correct for non-atomic absorption.
Pd (Palladium)

A.W. 106.4

Preparation of Standard Solutions

Recommended Standard Materials
Ammonium chloropalladite (NH₄)₂PdCl₄, 99.9%

Solution Technique
Dissolve 2.672 g of ammonium chloropalladite in water and dilute to 1 liter to give 1000 µg/mL Pd.

Recommended Instrument Parameters

</tr>
</tbody>
</table>

Flame Emission

Wavelength 363.5 nm
Slit width 0.1 nm
Fuel acetylene
Support nitrous oxide

Interferences

In the air-acetylene flame the atomic absorption signal is depressed in the presence of aluminium, cobalt or nickel at all concentrations and by hydrofluoric acid. The depression is eliminated in the presence of lanthanum (5000 µg/mL as chloride) or EDTA (0.01 M). The interference can be reduced by using a more oxidizing flame and by taking measurements higher in the flame. A nitrous oxide-acetylene flame can be used to overcome the interferences, but the sensitivity is much poorer.

<td>0.2</td>
<td>5–1600</td>
</tr>
</tbody>
</table>

Flame Emission

Wavelength 369.2 nm

Slit width 0.1 nm

Fuel acetylene

Support nitrous oxide

Interferences

In an air-acetylene flame, most other elements interfere and the interference depends unpredictably on their concentration. Phosphoric and sulfuric acids depress the signal (constant above 10% concentration). Alkali metal sulfates, on the other hand, enhance the signal strongly although other sulfates give mixed results.

Releasing agents mentioned in the literature include:

1. 3% \(\text{NaHSO}_4\) in 10% HCl
2. 1% La as \(\text{La}_2(\text{SO}_4)_3\) in 2% HCl
3. 1 mg/mL U as uranyl nitrate

although these reagents are not completely effective in the presence of the other noble metals.

In a nitrous oxide-acetylene flame most of these interferences do not arise; only ruthenium and iridium interfere and 0.5% Zn suppresses these effects.

References

Ru (Ruthenium)

A.W. 101.1

Preparation of Standard Solutions

Recommended Standard Materials

Ruthenium chloride RuCl₃.3H₂O A.R. Grade

Solution Technique

Dissolve 2.052 g of RuCl₃.3H₂O in 50 mL 1:4 hydrochloric acid and dilute to 1 liter to give 1000 μg/mL Ru.

Recommended Instrument Parameters

Atomic Absorption

<td>15–1600</td>
</tr>
</tbody>
</table>

Flame Emission

Wavelength 372.8 nm

Slit width 0.1 nm

Fuel acetylene

Support air

Interferences

In an air-acetylene flame most other elements and most acids interfere in an unpredictable manner. The only releasing agent discovered so far is uranyl nitrate (4% w/v U), which overcomes all interferences except the depression due to Ti(III).

The nitrous oxide flame is recommended to remove many interferences. It has been found that the sensitivity was improved by adding 0.1 M lanthanum nitrate and 0.8 M hydrochloric acid.

Mutual interference with the other noble metals has been observed in the air-acetylene flame. Uranium reduces these interferences.

Neutral solutions of ruthenium are unstable.

References

Sb (Antimony)

A.W. 121.75

Preparation of Standard Solutions

Recommended Standard Materials

Antimony metal granules 99.99%
Potassium antimonyl tartrate 99.99%

Solution Technique

Dissolve 1.000 g antimony in 100 mL hydrochloric acid containing 2 mL nitric acid, and dilute to 1 liter to give 1000 µg/mL Sb as Sb(V) in 10% hydrochloric acid. Make all further dilutions with 10% hydrochloric acid, or add 1% tartaric acid to prevent precipitation of antimony oxychlorides.

Recommended Instrument Parameters

Atomic Absorption

Working Conditions (Fixed)

Lamp current 10 mA
Fuel (Note 1) acetylene
Support air
Flame stoichiometry oxidizing

Note 1: The nitrous oxide-acetylene flame may also be used but shows reduced sensitivity.

Flame Emission

Wavelength 259.8 nm
Slit width 0.1 nm
Fuel acetylene
Support nitrous oxide

Interferences

In an air-acetylene flame, copper and nickel depress the signal, especially in a reducing flame. A more oxidizing flame removes the effect.

It has been suggested that the presence of excess oxidant in the solution depresses the absorbance, although for pure solutions in either oxidation state no differences in absorbance have been found. It is essential during sample preparation to avoid boiling antimony solutions containing chloride, as otherwise some antimony will be lost.

Vapor Generation Method

At low concentrations, this element can be determined by the vapor generation technique. Details of the appropriate procedures are given in the operation manual supplied with the Agilent vapor generation accessory. See also Reference 5.

**Interferences**

Scandium is partially ionized in the nitrous oxide-acetylene flame. To suppress ionization, add potassium nitrate or chloride solution to give a final concentration of 2000 μg/mL potassium in all solutions including the blank.

Sulfate or fluoride anions strongly suppress scandium absorption even when these interferents are only present in similar quantities to scandium.

Many cations suppress or enhance the absorption when present in one hundred fold excess.

To minimize the effects of these interferences, avoid using sulfate or fluoride where possible and ensure that the standard solutions contain the same reagents and major matrix elements at approximately the same concentration.

**Atomic Absorption**

**Working Conditions (Fixed)**

- Lamp current 10 mA
- Fuel acetylene
- Support nitrous oxide
- Flame stoichiometry strongly oxidizing; red cone 0.25 cm

An air-acetylene flame can also be used but the sensitivity is poorer and chemical interferences are significant.

**Working Conditions (Variable)**

- Wavelength (nm) 460.7
- Slit width (nm) 0.5
- Optimum working range 0.02–10 (μg/mL)

**Flame Emission**

- Wavelength 460.7 nm
- Slit width 0.1 nm
- Fuel acetylene
- Support nitrous oxide

**Interferences**

In the air-acetylene flame, silicon, aluminium, titanium, zirconium, phosphate and sulfate depress the signal at all concentrations. These effects can be removed by adding 1% lanthanum as nitrate or chloride to all solutions, or 0.01 M EDTA with 2000 μg/mL lanthanum.

In the nitrous oxide-acetylene flame these interferences do not occur.

Strontium is partially ionized in all flames. To suppress ionization, add potassium nitrate or chloride solution to give a final concentration of 2000 μg/mL potassium in all solutions including the blank.

**Flame Emission**

Wavelength 481.3 nm

Slit width 0.1 nm

Fuel acetylene

Support nitrous oxide

**Interferences**

Fluoride and ammonium ions in the absence of alkali metals increase the absorbance signal. In the presence of alkali metals and fluoride the absorbance is depressed. Sulfate depresses the absorbance, and phosphate enhances it up to 2% phosphoric acid — higher concentrations of phosphate depress the absorbance.

In the absence of alkali metals, the addition of ammonium fluoride to all solutions (0.1 M) gives improved sensitivity and reduces acid interferences. In the presence of alkali metals no releasing agents are known. Tantalum (V) cupferrate can be extracted from 0.5% tartrate systems at pH 0 with isoamyl alcohol.

Tantalum as the fluoride is extracted from 6 M sulfuric acid, 10 M hydrofluoric acid + 2.2 M ammonium fluoride medium into methyl isobutyl ketone.

It has been found that the addition of 2000 µg/mL of aluminium improves the linearity of tantalum determination.

Flame Emission

Wavelength 214.3 nm
Slit width 0.1 nm
Fuel acetylene
Support nitrous oxide

The determination of tellurium by flame emission is not recommended.

Interferences

No severe interferences have been encountered in the air-acetylene flame.

At low tellurium concentrations, acids and dissolved carbon dioxide can absorb significant amounts of radiation. It is recommended to check for background absorption by using a background corrector.

Vapor Generation Method

At low concentrations, this element can be determined by the vapor generation technique. Details of the appropriate procedures are given in the operation manual supplied with the Agilent vapor generation accessory. See also Reference 3.

Interferences

Most metallic elements enhance the titanium absorbance signal at concentrations above 500 μg/mL, probably by competing with titanium for the available oxygen in the flame and reducing the refractory titanium oxide. Sodium above 1000 μg/mL depresses the signal; fluoride, chloride, and ammonium ions enhance it. Releasing agents include:

1000 μg/mL Al in HCl
2000 μg/mL KCl
0.1 M NH₄F

</tr>
</tbody>
</table>

Flame Emission
Wavelength 360.1 nm
Slit width 0.1 nm
Fuel acetylene
Support nitrous oxide

Interferences
Zirconium is ionized in this flame and 0.1% potassium (as chloride) should be added to suppress ionization.

It is best to avoid oxygen containing anions (sulfate, nitrate) which tend to suppress the absorbance.

Hydrofluoric acid (3%) enhances the signal but at higher concentration gives a slight depression. Ammonium ion and chloride ion (0.1 M) and neutral fluoride compounds give enhancement and remove at least some of the metallic interferences. The addition of ammonium fluoride (0.1 M) has been recommended. The effects are minimized with a more oxidizing flame but sensitivity is reduced.

Addition of aluminium chloride has been found to improve the sensitivity and linearity.

3. Standard Conditions (Indirect Methods)

Chloride, Cl 83
Phosphate, PO₄ and Silicate, SiO₃ 86
Sulfate, SO₄ 89

Chloride, Cl

A.W. 35.45

The first step in determining chloride by atomic absorption spectrometry is to quantitatively precipitate silver chloride by the addition of a known amount of silver nitrate.

The amount of chloride in the original sample is then determined by either of two methods:

- The determination of excess silver in the solution after the precipitated silver chloride has been removed.

- Redissolving the precipitate in ammonia and analyzing the ammoniacal solution for the recovered silver.

In both methods the conditions used are the standard conditions applicable to the normal atomic absorption determination of silver. Aqueous silver standards are used in the calibration. When the sample solution contains very low concentrations of chloride, an alternative method of calibration is to employ standard solutions of sodium chloride which contain amounts of chloride similar to that expected in the sample. The sodium chloride solutions are treated in the same way as the sample and can then be used as secondary standards for the determination of chloride in the sample.

Silver Standard Conditions

Preparation of Standard Solutions

Recommended Standard Materials

Silver metal strip or wire 99.99%
Silver nitrate AgNO₃ 99.99%

Solution Technique

Dissolve 1.000 g of silver strip or wire in 20 mL 1:1 nitric acid and dilute quantitatively to 1 liter to give 1000 μg/mL Ag.

References

**Method 1**

**Range**
0.5–5.0 mg Cl

**Interferences**
Iodide, bromide, cyanide and sulfide interfere by precipitating as silver compounds. Chromate interference is minimized under the dilute acid conditions specified.

**Reagents**
Silver solution: Refer to silver standard conditions above. Prepare a solution containing 1000 mg/L Ag.

Nitric acid: Extra pure, chloride-free (S.G. 1.40).

**Sample Preparation**
Place an aliquot of sample solution, containing 0.5 to 5.0 mg of chloride, in a 200 mL volumetric flask. Add 20 mL of 1000 mg/L silver solution and 1 mL chloride-free nitric acid. Make up to volume with distilled water. The solution contains 100 mg/L Ag.

Allow the mixture to stand overnight in a dark place to prevent photochemical reactions taking place. Centrifuge an aliquot of the supernatant liquid slurry for 10 minutes. For analysis, take 10 mL of the clear solution and dilute to 100 mL with distilled water. The solution contains 10 mg/L excess silver.

**Standard Preparation**
Refer to silver standard conditions above.

Prepare a standard containing 50 mg/L Ag in 1% (v/v) chloride-free nitric acid.

Prepare calibration standards containing 0, 1.0, 2.5, 5.0, 7.5, 10.0 mg/L Ag.

**Instrument Parameters**
Refer to silver standard conditions above.

Use the 338.3 nm wavelength.

**Analysis**
Take replicate absorbance readings of the sample and standard solutions. Compare these absorbances and calculate the concentration of excess silver in the sample solution.

\[
\text{Excess silver (mg/L)} = \frac{\text{mg/L Ag} \times \text{dilution factor}}{100}
\]

Therefore:

\[
\text{Amount of chloride (mg)} = \frac{100 - \text{concentration of excess silver chloride in (mg/L)}}{0.329} \times \frac{\text{sample solution volume (mL)}}{1000}
\]

\[
\text{Concentration of chloride (mg/L)} = \frac{\text{amount of chloride (mg)}}{\text{volume of sample aliquot (liter)}}
\]

**Method 2**

**Range**
0.5–5.0 mg chloride

**Interferences**
Bromide and cyanide interfere by precipitation silver compounds which are soluble in ammonia. Iodide and chromate interference is minimized under the conditions specified.

**Reagents**
Silver solution: Refer to silver standard conditions above. Prepare a solution containing 1000 mg/L Ag.

Ammonia solution: Dilute extra pure (50% v/v) ammonia solution (S.G. 0.91) 1:1 with distilled water.

Nitric acid: Extra pure, chloride-free (S.G. 1.40)

**Sample Preparation**
Place an aliquot of sample containing 0.5 to 5.0 mg of chloride in a 250 mL covered beaker. Add 20 mL of 1000 mg/L silver solution and 1 mL chloride-free nitric acid. Dilute to approximately 200 mL with distilled water and allow to stand overnight in a dark place.
Filter the solution through a sintered glass crucible (porosity 3). Wash the precipitate twice with 10 mL aliquots of 1% (v/v) nitric acid and discard the washings.

Dissolve the precipitate in 10 mL of 50% (v/v) ammonia solution. Use a second 10 mL aliquot to complete the dissolution and rinse the vessel. Wash twice with 5 mL distilled water. Combine the ammonia solutions and washings, transfer to a 100 mL volumetric flask and make up to volume with distilled water.

For analysis, take 5 mL of prepared solution and dilute to 100 mL with distilled water. For a sample containing 5.0 mg chloride, the analytical solution will contain approximately 7.5 mg/L Ag.

**Standard Preparation**

Refer to silver standard conditions above.

Prepare a standard containing 50 mg/L Ag in 1% (v/v) chloride-free nitric acid.

Prepare calibration standards containing 0, 1.0, 2.5, 5.0, 7.5, 10.0 mg/L Ag.

**Instrument Parameters**

Refer to silver standard conditions above.

Use the 338.3 nm wavelength.

**Analysis**

Take replicate absorbance readings of the sample and standard solutions. Compare the absorbances and calculate the concentration of silver in solution and hence the concentration of chloride in the sample.

Concentration of $\text{Ag} = \frac{\text{mg/L Ag} \times \text{dilution factor}}{\text{mg/L}}$

Amount of chloride in sample solutions $= \frac{\text{concentration of silver found}}{\text{mg/L}} \times 0.329 \times \frac{\text{sample solution volume (mL)}}{1000}$

Concentration = amount of chloride (mg) / volume of sample aliquot (mg/L)
Standard Conditions (Indirect Methods)

Phosphate, PO₄ and Silicate, SiO₃

M.W. 94.97, 76.09

Phosphate and silicate can be indirectly determined by atomic absorption spectrometry by the estimation of the molybdenum content of certain molybdate complexes.

Both phosphate and silicate ions form heteropoly acid complexes with acidic molybdate solutions. To prevent mutual interference in the atomic absorption analysis, the complexes are selectively separated by solvent extraction. The heteropoly acids are then decomposed by treatment with a basic buffer solution to liberate the molybdenum which is then determined by atomic absorption.

Phosphate

The method depends upon the separation of the two heteropoly acids by means of extraction with diethyl ether. The molybdisphosphoric acid is retained in the organic phase and is back-extracted with a basic aqueous buffer solution. The heteropoly acid complex is decomposed to leave the molybdenum in the aqueous phase.

Standard phosphorous solutions are treated in a like manner and the molybdenum absorbance calibrated against known amounts of phosphorous. The phosphorous content of the original sample is then calculated by comparison with the phosphorous standards.

Silicate

The molybdosilicic acid complex is retained in the aqueous phase of the diethyl ether extraction. To isolate the complex, the aqueous solution is then extracted into a diethyl ether:pentanol mixture. The organic heteropoly complex is decomposed by back-extraction with basic buffer solution to leave the molybdenum in the aqueous phase.

Standard silicon solutions are treated in a like manner and the molybdenum absorbance calibrated against known amounts of silicon. The silicon content of the original sample is then calculated by comparison with the silicon standards.

References

Molybdenum Standard Conditions

Preparation of Standard Solutions

Recommended Standard Materials

Molybdenum metal strip or wire 99.99%

Solution Technique

Dissolve 1.000 g of molybdenum strip or wire in hot concentrated nitric acid, cool and dilute to 1 liter to give 1000 μg/mL Mo.

Recommended Instrument Parameters

Working Conditions (Fixed)

| Lamp current | 7 mA |
| Fuel         | acetylene |
| Support      | nitrous oxide |
| Flame stoichiometry | strongly reducing; red cone 2–3 cm |

Working Conditions (Variable)

Phosphate

Range
0.01–0.13 mg phosphorous
0.03–0.4 mg phosphate

Reagents

Ammonium molybdate solution (10% w/v)
Dissolve 25.00 g of A.R. ammonium molybdate in distilled water and dilute to 250 mL.

Buffer solution
Dissolve 53.30 g of A.R. ammonium chloride in distilled water. Add 70 mL of A.R. ammonium solution and dilute to 1 liter.

Sample Preparation

Formation of heteropoly acids
Place 10 mL of sample solution in a 125 mL separating funnel. Add 1 mL 1:2 hydrochloric acid and adjust the total volume to approximately 50 mL. Add 4 mL ammonium molybdate solution, swirl to mix and allow to stand for 10 minutes; the pH of the solution should be approximately 1.3. Add 5 mL concentrated hydrochloric acid, mix and allow to stand for a further 5 minutes.

Separation of molybdophosphoric acid and molybdosilicic acid
Add 45 mL A.R. diethyl ether and shake vigorously for 3–4 minutes. Allow the phases to separate and transfer the entire lower aqueous layer to another separating funnel for the subsequent determination of silicon. Wash the tip of the original funnel with distilled water and add the washings to the aqueous layer.

Decomposition of molybdosilicic acid
To remove excess molybdenum, add 10 mL 1:10 hydrochloric acid to the ether extract and mix well. Discard the acid layer, washing the tip of the funnel. Add 30 mL of buffer solution, shake for 30 seconds and withdraw the aqueous layer into a 50 mL volumetric flask. Repeat with a further 15 mL of buffer solution. Dilute the combined aqueous layers to 50 mL with distilled water. Determine the molybdenum absorbance on this solution.

Standard Preparation
Dissolve 2.200 g of A.R. potassium dihydrogen phosphate (KH₂PO₄) in distilled water and dilute to 1 liter to give a solution containing 500 mg/L phosphorous.
Prepare a standard containing 10 mg/L phosphorous by dilution of the 500 mg/L phosphorous solution.
Take 1, 2, 5, 10 mL aliquots of the 10 mg/L phosphorous standard to give 0.01, 0.02, 0.05, 0.1 mg phosphorous. Treat the standard aliquots in the same manner as the sample solution and determine the molybdenum absorbance for this range of phosphorous.

Instrument Parameters
Refer to molybdenum standard conditions above.
Use the 313.3 nm wavelength.
Scale expansion may be required.

Analysis
Take replicate absorbance readings of the sample and phosphorous standard solutions. Compare these absorbances and calculate the amount of phosphorous in the sample.

Concentration = amount of phosphorous (mg) 
/volume of sample aliquot (mg/L)  
(liter)

Silicate

Range
0.01–0.13 mg silicon

Reagents

Diethyl ether-pentanol solution (5:1)
Prepare a mixture fresh daily.

Sample Preparation
Refer to phosphate section.
Decomposition of Molybdosilicic Acid

To the aqueous molybdosilicic fraction obtained from the separation of the heteropoly acids, add 5 mL hydrochloric acid and mix well. Allow to stand for 5 minutes, add 20 mL 5:1 diethyl ether-pentanol solution and shake vigorously for 3 minutes. Allow to settle and discard the aqueous layer containing excess molybdenum. Wash the organic extract with two 25 mL portions of 1:10 hydrochloric acid shaking for 30 seconds each time. Discard the washings and rinse the tip of the funnel with distilled water.

Add 30 mL of buffer solution, shake for 30 seconds and withdraw the aqueous layer into a 50 mL volumetric flask. Repeat with a further 15 mL of buffer solution. Dilute the combined aqueous layers to 50 mL with distilled water. Determine the molybdenum absorbance on this solution.

Standard Preparation

Fuse 2.14 g of A.R. silicon dioxide with 8 g of A.R. sodium hydroxide in a zirconium crucible. Heat to a dull red heat until a clear melt is obtained. Cool, dissolve the melt in 100 mL of 1:3 hydrochloric acid and make up to 1 liter to give a solution containing 1000 mg/L silicon. Prepare a standard containing 10 mg/L Si by dilution of the 1000 mg/L silicon solution.

Take 1, 3, 5, 10 mL aliquots of the 10 mg/L silicon standard to give 0.01, 0.02, 0.05, 0.1 mg silicon. Treat the standard aliquots in the same manner as the sample solution and determine the molybdenum absorbance for this range of silicon.
**Sulfate, SO₄**

**M.W. 96.06**

The quantitative reaction of sulfate with barium chloride to produce barium sulfate is used as a basis for the indirect determination of the sulfate ion by atomic absorption spectrometry. The amount of sulfate in the original sample is then estimated by either of two methods:

- The determination of excess barium in the solution after the precipitated barium sulfate has been removed by filtration.
- The redissolution of the precipitate in EDTA solution followed by the determination of the recovered barium.

In both methods the conditions used for the analysis of the barium content are those applicable to the normal atomic absorption determination of barium.

The barium sulfate is precipitated under controlled conditions of temperature and acidity to minimize errors caused by the solubility of the barium sulfate at low concentrations. In addition, calibration of the method is best achieved by determining the barium content of a range of sulfate standards which are subject to the same treatment as the sample solutions. A series of recovery values are used to check for coprecipitation by other species.

**Interferences**

Barium is partially ionized in the nitrous oxide-acetylene flame. To suppress ionization, add potassium nitrate or chloride solution to give final concentration of 2000 \( \mu \text{g/mL} \) potassium in all solutions including the blank.

**Method 1**

**Range**

0.2–2.0 mg SO₄

**Reagents**

Barium solution (200 mg/L Ba): Refer to barium standard conditions above. Prepare a solution containing 200 mg/L Ba by dilution of a 1000 mg/L barium standard.

Hydrochloric acid (0.2 M): Dilute 1.8 mL of concentrated hydrochloric acid to 100 mL with distilled water.
Sample Preparation

Transfer 10 mL of sample solution to a 50 mL volumetric flask. Place in a water bath, add 5 mL 0.2 M hydrochloric acid and allow the temperature to reach 90–95°C. Add 10 mL of 200 mg/L barium solution slowly with frequent mixing. Continue to warm on the water bath for about 5 minutes after the addition of the barium solution. Allow to cool and make up to volume with distilled water. Allow to stand overnight. Decant off a portion of the supernatant liquid and centrifuge if necessary to obtain a clear solution. Take 10 mL of clear solution, add 1 mL of a solution containing 100 g/L potassium and dilute to 50 mL with distilled water. For a sample containing 2.0 mg sulfate, the analytical solution will contain approximately 4.5 mg/L excess barium with 2000 mg/L added potassium.

Standard Preparation

Barium Standards

Refer to barium standard conditions above.

Prepare a standard containing 50 mg/L Ba.

Prepare standards containing 0, 2.5, 5, 7.5, 10, 15, 20 mg/L Ba with the addition of 2000 mg/L potassium.

Sulfate Standards

1000 mg/L sulfate solution: Dissolve 1.4797 g of dried A.R. anhydrous sodium sulfate in distilled water and dilute to 1 liter. The solution will contain 1000 mg/L sulfate.

Prepare standards containing 10, 25, 50, 100, 150, 200 mg/L sulfate.

Take 10 mL aliquots of the sulfate standards and treat them according to the procedure given in sample preparation. The analytical solutions will contain 0.01, 0.025, 0.05, 0.1, 0.15, 0.2 mg sulfate.

Instrument Parameters

Refer to barium standard conditions above.

Use the 553.6 nm wavelength.

Analysis

Take replicate absorbance readings of the barium in the sample and sulfate standard solutions.

Compare these absorbances and calculate the concentration of sulfate in the sample.

Amount of sulfate = standard sulfate (mg) in sample (mg) x dilution factor

Concentration of sulfate (mg/L) / volume of sample aliquot (liter)

Recovery Values

The estimation of sulfate by the quantitative precipitation of barium sulfate is prone to errors of coprecipitation, non-selectivity and operator technique. In order to check for these errors, the excess barium resulting from the precipitation of standard sulfate is compared with standard barium solutions.

Take replicate absorbance readings of the barium in the standard sulfate and standard barium solutions.

Compare these absorbances and calculate the concentration of available sulfate in the sulfate standards.

excess barium = mg/L Ba x dilution factor (mg/L)

Amount of sulfate = [80 - concentration of excess sulfate (mg) / barium (mg/L)] x 0.704 x solution volume (mL) / 1000

Concentration of sulfate (mg/L) / volume of aliquot (liter)

The concentration of available sulfate found in the standard sulfate solutions is then compared with the initial added values to give a percentage yield.

%Recovery = concentration of sulfate found (mg/L) / initial concentration of sulfate standard (mg/L) x 100
Method 2

**Range**
0.2–2.0 mg SO₄

**Sample Preparation**
Take 10 mL of sample solution, place in a 100 mL covered beaker and precipitate the barium sulfate using the conditions given in Method 1; final volume of solution approximately 50 mL. Allow to stand overnight and filter through a sintered glass crucible (porosity 3). Wash the precipitate with two 5 mL portions of distilled water.

**NOTE** An alternative procedure is to centrifuge the solution; discard the supernatant liquid; add 10 mL of distilled water and stir thoroughly; centrifuge and discard the supernatant liquid again.

Redissolve the precipitate in 8 mL 1% (w/v) sodium EDTA solution by warming gently. Transfer to 100 mL volumetric flask and make up to volume with distilled water. For a sample solution containing 2.0 mg sulfate, the prepared solution will contain approximately 29 mg/L Ba.

**Standard Preparation**

**Barium Standards**
Refer to barium standard conditions above.
Prepare a standard containing 100 mg/L Ba.
Prepare standards containing 0, 2, 5, 10, 15, 20, 25, 30 mg/L Ba with the addition of 1% (w/v) sodium EDTA at a concentration of 8 mL/100 mL solution.

**Sulfate Standards**
Refer to Method 1.
Prepare standards containing 10, 25, 50, 100, 150, 200 mg/L sulfate.

Take 10 mL aliquots to give standards containing 0.1, 0.25, 0.5, 1.0, 1.5, 2.0 mg sulfate. Treat the standard aliquot in the same manner as the sample solution and determine the barium absorbance for this range of sulfate.

**Instrument Parameters**
Refer to barium standard conditions above.
Use the 553.6 nm wavelength.

**Analysis**
Take replicate absorbance readings of the barium in the sample and sulfate standard solutions. Compare these absorbances and calculate the concentration of sulfate in the sample.

\[
\text{Amount of sulfate} = \frac{\text{standard sulfate (mg) x in sample (mg)}}{\text{dilution factor}}
\]

Concentration of sulfate = \( \frac{\text{amount of sulfate (mg)}}{\text{sulfate (mg/L) x volume of sample aliquot (liter)}} \)

**Recovery Values**
Refer to Method 1.
Take replicate absorbance readings of the barium in the standard sulfate and standard barium solutions.
Compare these absorbances and calculate the concentration of available sulfate in the sulfate standards.

\[
\text{Amount of sulfate found} = \frac{\text{concentration of barium sulfate (mg)} \times 0.704 \times \text{solution volume (mL)}}{1000}
\]

Concentration of sulfate = \( \frac{\text{amount of sulfate (mg)}}{\text{volume of sample aliquot (liter)}} \)

The concentration of available sulfate found in the standard sulfate solutions is then compared with the initial values to give a percentage yield.

\[
\%\text{Recovery} = \frac{\text{concentration of sulfate found (mg/L)}}{\text{initial concentration of sulfate standard (mg/L) x 1000}}
\]

**Agriculture**

**Laying Meal**

**Mn (Manganese)**

**Typical Analysis**

Mn 0.01%

**Sample Preparation**

Wet-ash 2.5 g samples with nitric acid and perchloric acid. Dilute to 100 mL to give approximately 2.5 μg/mL Mn in solution.

**Standard Preparation**

Prepare calibration standards containing 0, 2.5, 5, 10 μg/mL Mn, matching the sample in perchloric acid content.

**Orchard Leaves (NBS Standard)**

**As (Arsenic)**

**Vapor Generation Technique**

At low concentrations, this element can be determined by the vapor generation technique. Details of the appropriate procedures are given in the operation manual supplied with the Agilent vapor generation accessory. Refer also to Agilent Instruments At Work, No. AA-38.

**Optimum Range**

50–300 ng arsenic i.e., in this preparation 0.005–0.30 μg/mL in solution or 5–30 μg/g in the sample.

**Interferences**

At the 193.7 nm wavelength, non-atomic absorption due to molecular species will necessitate the use of background correction.

Chemical interferences can be encountered in the generation of arsine. Oxidizing agents can prevent the reaction entirely. Excess nitric acid in particular must be absent from the test solution.

**Special Reagents**

Ensure that all reagents are as free as possible from arsenic.

- Hydrochloric acid – Aristar Grade
- Sodium borohydride – Laboratory Grade

To prepare 5% solution, dissolve 5 g of sodium borohydride in distilled water containing 0.1 g/100 mL of sodium hydroxide.
Methodology

Sample Preparation

Weigh 1.000 g of dried orchard leaves standard material and place in a clean crucible. Mix with 8 mL or 50% w/v magnesium nitrate ashing aid. Place the crucible on the hot plate and bring the contents to boil. Allow to foam, but ensure that no sample is lost. When the foaming ceases, cover the crucible and transfer to a muffle furnace set at 200°C. After two hours raise the temperature to 500°C and ash for about 8 hours.

Dissolve the residual ash in 2–5 mL hydrochloric acid and transfer to a 100 mL volumetric flask. Make up to volume with distilled water.

Standard Preparation

Prepare calibration solutions containing 0, 0.1, 0.2, 0.3 μg/mL (mg/L) arsenic so that 1 mL aliquots will contain 0, 100, 200, 300 ng arsenic.

Plant Material

Ca (Calcium)

Typical Analysis

Ca 150 μg/g  K 0.8%  Mg 0.36%
Na 20 μg/g  Cu 0.004%

Interferences

Phosphorous in the plant material will depress the calcium absorbance by 35–50%. This is overcome by the use of a nitrous oxide-acetylene flame.

Calcium is partially ionized in this flame. To suppress ionization, add potassium nitrate or chloride to give a final concentration of 2000 μg/mL potassium in all solutions including the blank.

Sample Preparation

Moisten 1.000 g dried, powdered plant material with a few drops of water. Add 5 mL nitric acid and evaporate to moist salts. Repeat the digestion until no visible charred material is present.

Cool, add 5 mL nitric acid and 5 mL perchloric acid. Heat slowly until the solution has cleared, and then evaporate to moist salts.

WARNING

Explosion Hazard

Organic perchlorates are explosive. Refer to the warning message on Page 3 of this book.

Dissolve the residue in 2 mL nitric acid and dilute to 50 mL with the addition of 2000 μg/mL potassium. For 150 μg/g Ca, the solution concentration will be approximately 3 μg/mL Ca.

Standard Preparation

Refer to calcium standard conditions.

Prepare calibration standards containing 0, 1, 3, 5 μg/mL Ca. Each solution must contain 2000 μg/mL added potassium.

Cu (Copper)

Typical Analysis

Refer to calcium in plant material.

Sample Preparation

Refer to calcium in plant material.

Weigh 2.500 g of dried, crushed material into a 250 mL beaker and carry out a controlled wet ashing with nitric and perchloric acids. Dilute to 50 mL. For highest accuracy a blank test on all reagents and glassware should be taken through the entire analysis.

For 0.0004% Cu, the solution concentration will be approximately 2 μg/mL Cu.

Standard Preparation

Refer to copper standard conditions.

Prepare standards containing 0, 1.0, 2.0, 3.0 μg/mL Cu in 1% perchloric acid.

Na (Sodium)

Typical Analysis

Refer to calcium in plant material.

Sample Preparation

Refer to sodium standard conditions. For 20 μg/g Na in the 1.000 g sample, the solution concentration will be 0.4 μg/mL Na.
Standard Preparation

Refer to sodium standard conditions.

Prepare calibration standards containing 0, 0.2, 0.4, 0.6 μg/mL Na, each containing in addition 2000 μg/mL K to approximately match the sample solution. Fresh standards should be prepared daily.

Tl (Thallium)

Range

0.3–30 μg/g

References

Reagents

Sodium hydroxide (50% w/v):
Dissolve 50 g of A.R. sodium hydroxide in distilled water. Cool, dilute to 100 mL with distilled water.

Sodium hydroxide 2.5 N:
Dissolve 10.00 g of A.R. sodium hydroxide in distilled water. Cool, dilute to 100 mL with distilled water.

Sulfuric acid 2.5 N:
Add 7 mL of concentrated sulfuric acid slowly, and with caution, to 80 mL distilled water. Cool, dilute to 100 mL with distilled water.

Sodium diethyldithiocarbamate (1% w/v):
Dissolve 0.500 g of A.R. sodium diethyldithiocarbamate in distilled water with gentle heating. Cool, dilute to 50 mL with distilled water.

NOTE

This solution must be freshly prepared for each series of determinations.

Sample Preparation

Place 5.000 g of biological material and 20 mL 1:1 nitric-sulfuric acid in a 100 mL Kjeldahl flask. Digest at 120–150°C to drive off oxides of nitrogen, taking care to prevent charring. If charring does occur, add 5 mL nitric acid, with caution, and continue heating as before (repeat the addition of excess nitric acid if necessary). When the initial reaction has ceased, heat more strongly to sulfur trioxide fumes; and take down to a final volume of about 10 mL.

Allow to cool to room temperature, add 50 mL distilled water in small amounts, rotating the flask to prevent localized boiling.

WARNING

The initial additions of water cause a vigorous reaction. Hold the flask with the neck pointing into the fume cupboard, away from the operator or else a serious injury could result.

Cool the flask in a container of running water. Add 50% (w/v) sodium hydroxide to neutralize the acid.

WARNING

Add the sodium hydroxide in small increments of 1–3 mL, cooling down between each addition to control the violent reaction or else a serious injury could result.

When most of the acid has been neutralized, as shown by a slowing down of the reaction, add a few drops of thymol blue indicator and continue the neutralization with the dropwise addition of 50% (w/v) sodium hydroxide. Transfer to a 100 mL volumetric flask and make up to volume with distilled water.
Methodology

Place 20 mL replicate aliquots into 50 mL stoppered test tubes or phials. Using a pH meter, adjust the pH of the solutions to 6–7 with 2.5 N sodium hydroxide and 2.5 N sulfuric acid. Add 2 mL 1% (w/v) sodium diethylthiocarbamate, stopper the vessel and shake for one minute to allow chelation to occur. Add 3 mL methyl isobutyl ketone and shake in a rapid, even manner for 4–5 minutes. Allow the phases to separate over 30 minutes. Use the clear, organic phase for analysis.

For 0.3 μg/g Tl, the organic portion will contain approximately 0.3 μg/mL Tl.

Standard Preparation

Refer to thallium standard conditions.

Prepare calibration standards containing 0, 0.5, 1, 5, 10, 20, 30 μg/mL Tl. Take 20 mL aliquots of the standard solution and adjust the pH, chelate and extract with methyl isobutyl ketone as above (see sample preparation).

Soil Extract

Ca (Calcium)

Range

50–3000 μg/g

Interferences

Inter-element chemical interferences are overcome by using a nitrous oxide-acetylene flame.

Calcium is partially ionized in this flame. To suppress ionization add potassium nitrate or chloride to give final concentration of 5000 μg/mL potassium in all solutions including blank.

Sample Preparation

Accurately weigh 10.00 g finely ground, representative soil sample (note 2) into a 250 mL conical flask. Add 50 mL of 1 N ammonium acetate solution with pH adjusted to 7.0. Shake vigorously for one hour and filter through ammonium acetate washed Whatman 540 paper. Make up the volume to 100 mL with distilled water (solution A for K). Dilute 10 mL of prepared solution to 100 mL with distilled water. Add 500 μg/mL potassium (solution B for Ca/Mg).

For sample with 300 μg/g Ca, the dilute solution will contain 3 μg/mL Ca.

Standard Preparation

Refer to calcium standard conditions.

References

Cu (Copper)

Range

0–20 μg/g Cu

Interferences

The copper absorbance is not affected by high amounts (up to 2000 μg/mL) of Al, Ca, Fe, K, Mg, Na present in the extraction solution(2).

Sample Preparation

Take a representative soil sample according to standard specification (for contamination surveys the taking of 6” depth samples is usually recommended).

Accurately weigh 10.00 g of dry, finely ground soil into a 100 mL conical flask. Add 30 mL of 0.05 M EDTA previously neutralized to pH 7.0 with purified ammonia. Shake the mixture vigorously for one hour and filter through an EDTA washed Whatman 540 paper. Adjust the filtrate volume to 50 mL with distilled water.

For 20 μg/g Cu, the sample solution will contain 4 μg/mL Cu.

Standard Preparation

Prepare calibration standards containing 0, 0.5, 1.0, 2.0, 5.0 μg/mL Cu using 0.05 M EDTA solution for dilutions. The standard solutions must contain the same major matrix elements as the sample solution at approximately the same concentration.
References

K (Potassium)
**Range**
0–80 μg/g

**Sample Preparation**
Refer to procedure recommended for calcium in soil extract.

Use original, undiluted solution; for 8 μg/g K, the solution will contain 0.8 μg/mL K.

**Standard Preparation**
Make up calibration standards containing 0, 0.2, 0.5, 1.0, 2.0 μg/mL K in 1 N ammonium acetate.

Mg (Magnesium)
**Range**
0–100 μg/g

**Interferences**
In the air-acetylene flame chemical interferences are overcome by the addition of a releasing agent such as strontium or lanthanum.

Analysis in the nitrous oxide-acetylene flame is free from inter-element interference.

**Sample Preparation**
Refer to procedure recommended for calcium. Use dilute solution. For 20 μg/g Mg, the solution will contain 0.2 μg/mL Mg.

**Standard Preparation**
Prepare calibration solutions containing 0, 0.1, 0.2, 0.5 μg/mL Mg in 1 N ammonium acetate.

Each solution should contain 5000 μg/mL potassium.

Zn (Zinc)
**Range**
0.01–5.8 μg/g

**Sample Preparation**
Refer to preparation of soil extract for copper analysis. For 5.8 μg/g Zn in the sample, solution will contain 1.16 μg/mL Zn.

**Standard Preparation**
Prepare standards containing 0, 0.5, 1.0, 2.0 μg/mL Zn. Use 0.05 M EDTA solution in dilution of the standards. Concentrations of elements, other than zinc, present in the sample solution should be matched in the standards.
Methodology

Biochemical

Whole Blood

Pb (Lead)

Reagents

- Water saturated methyl isobutyl ketone.
- Triton X-100/APDC (5% Triton X-100, 2% APDC).
  1. Dissolve 5.0 g of Triton X-100 in 50 mL distilled water.
  2. Dissolve 2.0 g of ammonium pyrrolidine dithio-carbamate (APDC) in 50 mL distilled water.

Warm gently to dissolve the material and flocculate the decomposition products. Filter through a Whatman No. 540 paper. Allow the filtrate to cool and place in a 250 mL separating funnel.

Add 20 mL of water-saturated MIBK, shake and allow to separate. Discard the organic layer and repeat extraction with further 20 mL of MIBK.

Drain the aqueous layer through the filter paper. Combine the solution prepared in 1 and 2. Store in the refrigerator in a dark bottle.

The reagent is stable for 10 days.

Sample Preparation

Pipette 4 mL aliquots of blanks, standards and whole blood samples into 10 mL polypropylene centrifuge tubes using the Oxford ‘Macro-Sampler’. For repeatable volumes of blood, expel the sample slowly while the pipette is vertical and the disposable tip is in contact with the side of the tube.

Add 1 mL of Triton X-100/APDC reagent. Cover the tube and mix thoroughly on the vortex mixer. Allow to stand for 15 minutes.

Carefully add 4 mL of water-saturated MIBK. Cap tightly and mix over a 10 minute period. Allow to stand for 5 minutes and centrifuge for 3 minutes at 3000 rpm.

Use the organic phase for determination.

Standard Preparation

Intermediate standards: Dilute 2, 5, 10, 15, 20 mL of lead stock solution to 100 mL with distilled water in acid-washed volumetric flasks. The resulting solutions will contain 20, 50, 100, 200 μg/mL Pb.

Working standards in blood matrix: Pipette 1 mL of aliquots of all intermediate standard solutions into five 100 mL volumetric flasks. Make up to volume with pooled blood. Prepared standards will contain 0.2, 0.5, 1.0, 1.5, 2.0 μg/mL Pb.

Aqueous working standards: Repeat procedures for blood standards but use distilled, deionized water for dilutions.

Blood Serum

Ca (Calcium)

Range 7.5–13.0 mg/100 mL (75–130 μg/mL)

Typical Analysis

10.0 mg/100 mL (100 μg/mL) Ca

Interferences

Inter-element interferences are overcome by using a nitrous oxide-acetylene flame.

Calcium is partially ionized in the nitrous oxide-acetylene flame. To suppress ionization add potassium nitrate or chloride to give final concentration of 5000 μg/mL potassium in all solutions including the blank.

Sample Preparation

Dilute 0.1 mL serum to 5 mL with the addition of 5000 μg/mL potassium.

For 100 μg/mL Ca the solution concentration will be approximately 2 μg/mL Ca.

Standard Preparation

Refer to calcium standard conditions.

Prepare calibration standards containing 0, 1, 2, 3 μg/mL Ca. Each solution must contain 5000 μg/mL potassium.
Methodology

Fe (Iron)

Range
90–250 μg/100 mL Fe

Interferences
The organic solvent used in this method acts as a supplementary fuel in the flame. It is essential to maintain thermal and optical equilibrium in the flame by aspirating a solvent blank continuously between samples.

Sample Preparation
Place 2 mL of serum into a 15 mL centrifuge tube, add 1 mL of 1 N hydrochloric acid. Mix by swirling and stand for 10 minutes.

Add 8 mL of 10% trichloracetic acid, cap the tube with a small square of plastic film, shake vigorously for 10 seconds and stand for 30 minutes.

After centrifugation, pipette 8 mL of the supernatant liquid into a 15 mL test tube, add 1.5 mL of 30% potassium acetate and 2 mL of alcoholic solution of bathophenan throline (25 mg/100 mL). Mix and let stand for 5 minutes. Add 1.0 mL of methyl isobutyl ketone, cap and shake vigorously for 10 seconds.

Let stand until the phases separate; use the organic phase in subsequent determination.

Standard Preparation
Refer to iron standard conditions.
Prepare calibration standards containing 0, 0.5, 1.0, 2.0 μg/mL Fe.

Extract 2 mL of the standard solutions with methyl isobutyl ketone, adding all reagents present in the sample solutions.

K (Potassium)

Range
3.5–6.5 meq/L (135–255 μg/mL) K

Sample Preparation
Dilute 0.1 mL of serum or plasma to 5 mL.

For 6.5 meq/L K, the solution concentration will be approximately 5 μg/mL K.

Standard Preparation
Refer to potassium standard conditions.

Prepare calibration standards containing 3, 4, 5 μg/mL K, (0.075 0.1 0.125 meq/L K) each containing 2 μg/mL Na.

Alternatively, use a calibrated reference serum diluted according to the manufacturer’s instructions. Suitable standards include:
‘DADE’ brand ‘Monitrol’ Reference Serum (Sold as ‘CHEMONITOR’ in U.K. and France), and
Warner Chilcott brand ‘CALIBRATE’ Reference Serum.

Li (Lithium)

Range
0.5–1.5 meq/L (3.5–10.5 μg/mL) Li

Sample Preparation
Dilute 0.5 mL of serum or plasma to 2.5 mL.

For 1.5 meq/L Li, the solution concentration will be approximately 2 μg/mL Li.

Standard Preparation
Refer lithium standard conditions.
Prepare calibration standards containing 0.5, 1.0, 1.5, 2.0 μg/mL Li, (0.07, 0.14, 0.21, 0.28 meq/L Li).

Alternatively, use a calibrated reference serum diluted according to the manufacturer’s instructions. Suitable standards include:
‘DADE’ brand ‘Monitrol’ Reference Serum (Sold as ‘CHEMONITOR’ in U.K. and France).

Mg (Magnesium)

Range
1.5–5.8 mg/100 mL (15–58 μg/mL)

Typical Analysis
2.2 mg/100 mL (22 μg/mL)

Interferences
Chemical interferences are limited to a protein viscosity effect and phosphate ions.
In the air-acetylene flame both are overcome by the addition of a releasing agent such as strontium (1500 μg/mL) or lanthanum (10000 μg/mL).
Methodology

The use of the nitrous oxide-acetylene flame, together with an ionization suppressor such as potassium, is preferred.

Sample Preparation

Dilute 0.1 mL plasma to 5 mL with the addition of 1 mL of a potassium chloride solution containing 25000 μg/mL potassium. For 22 μg/mL Mg, the solution concentration will be approximately 0.44 μg/mL Mg with 5000 μg/mL potassium added.

Standard Preparation

Refer to magnesium standard conditions.

Prepare calibration standards containing 0, 0.2, 0.4, 0.6 μg/mL Mg.

Each solution should contain 5000 μg/mL potassium.

Na (Sodium)

Range

120–150 meq/L (2760–3450 μg/mL) Na

Sample Preparation

Refer to potassium in blood serum.

For 150 meq/L Na, the solution concentration will be approximately 70 μg/mL.

Standard Preparation

Refer to sodium standard conditions.

Prepare calibration standards of 50, 60, 70 μg/mL Na, or 2.2, 2.6, 3.0 meq/L Na. Alternatively, calibrated reference standards can be used (see potassium in blood serum).

Biological Tissue

Tl (Thallium)

Range

0.3–30 μg/g

References

Reagents

Sodium hydroxide (50% w/v):
Dissolve 50 g of A.R. sodium hydroxide in distilled water. Cool, dilute to 100 mL with distilled water.

Sulfuric acid 2.5 N:
Add 7 mL of concentrated sulfuric acid slowly, and with caution, to 80 mL distilled water. Cool, dilute to 100 mL with distilled water.

Sodium diethyldithiocarbamate (15% w/v):
Dissolve 0.500 g of A.R. sodium diethyldithiocarbamate in distilled water with gentle heating. Cool, dilute to 50 mL with distilled water.

NOTE

This solution must be freshly prepared for each series of determinations.

Sample Preparation

Place 5.000 g of biological material and 20 mL 1:1 nitric-sulfuric acid in a 100 mL Kjeldahl flask. Digest at 120–150°C to drive off oxides of nitrogen, taking care to prevent charring. If charring does occur, add 5 mL nitric acid, with caution, and continue heating as before (repeat the addition of excess nitric acid if necessary). When the initial reaction has ceased, heat more strongly to sulfur trioxide fumes, and take down to a final volume of about 10 mL.

Allow to cool to room temperature, add 50 mL distilled water in small amounts, rotating the flask to prevent localized boiling.

WARNING

The initial additions of water cause a vigorous reaction. Hold the flask with the neck pointing into the fume cupboard, away from the operator or else a serious injury could result.

Cool the flask in a container of running water. Add 50% (w/v) sodium hydroxide to neutralize the acid.
Add the sodium hydroxide in small increments of 1–3 mL, cooling down between each addition to control the violent reaction or else a serious injury could result.

When most of the acid has been neutralized, as shown by a slowing down of the reaction, add a few drops of thymol blue indicator and continue the neutralization with the dropwise addition of 50% (w/v) sodium hydroxide. Transfer to a 100 mL volumetric flask and make up to volume with distilled water.

Place 20 mL replicate aliquots into 50 mL stoppered test tubes or phials. Using a pH meter, adjust the pH of the solutions to 6–7 with 2.5 N sodium hydroxide and 2.5 N sulfuric acid. Add 2 mL 1% (w/v) sodium diethyldithiocarbamate, stopper the vessel and shake for one minute to allow chelation to occur. Add 3 mL methyl isobutyl ketone and shake in a rapid, even manner for 4–5 minutes. Allow the phases to separate over 30 minutes. Use the clear, organic phase for analysis.

For 0.3 μg/g Tl, the organic portion will contain approximately 0.3 μg/mL Tl.

**Standard Preparation**

Refer to thallium standard conditions.

Prepare calibration standards containing 0, 0.5, 1, 5, 10, 20, 30 μg/mL Tl. Take 20 mL aliquots of the standard solution and adjust the pH, chelate and extract with methyl isobutyl ketone as above (see sample preparation).

**Chicken Plasma**

**Ca (Calcium)**

**Typical Analysis**

| Ca  | 160 μg/mL | Mg  | 24 μg/mL |
| Cu  | 1.6 μg/mL | Zn  | 2.2 μg/mL |

**Interferences**

The nitrous oxide-acetylene flame is used to overcome interferences from phosphates. Calcium is partially ionized in this flame. To suppress ionization, add potassium nitrate or chloride to give a final concentration of 2000 μg/mL potassium in all solutions including the blank.

**Sample Preparation**

Dilute 1 mL sample to 5 mL with distilled water. Centrifuge the solution for ten minutes to separate the protein matter. Decant the supernatant liquid into the original flask; use this clear solution for all subsequent operations.

Dilute 1 mL of the prepared solution to 25 mL with distilled water with the addition of potassium to a concentration of 2000 μg/mL. For 160 μg/mL Ca, the analytical solution will contain approximately 1 μg/mL Ca at a dilution of 1/125 the original sample.

**Standard Preparation**

Refer to calcium standard conditions.

Prepare calibration standards containing 0, 0.5, 1.0, 1.5 μg/mL Ca in 2000 μg/mL potassium.

**Cu (Copper)**

**Typical Analysis**

Refer to calcium in chicken blood plasma.

**Sample Preparation**

Refer to calcium in chicken blood plasma.

Use the centrifuged solution; no further dilution is required (dilution factor 1/5). For 1.6 μg/mL Cu, the solution concentration will be approximately 0.3 μg/mL Cu.

**Standard Preparation**

Refer to copper standard conditions.

Prepare calibration standards containing 0, 0.1, 0.2, 0.3, 0.4 μg/mL Cu.

**Mg (Magnesium)**

**Typical Analysis**

Refer to calcium in chicken blood plasma.
Methodology

Sample Preparation
Refer to calcium in chicken blood plasma.
Use the 1/125 dilution solution. For 24 μg/mL Mg, the solution concentration will be approximately 0.2 μg/mL Mg.

Standard Preparation
Refer to magnesium standard conditions.
Prepare calibration standards containing 0, 0.1, 0.2, 0.3 μg/mL Mg with 2000 μg/mL potassium added to match the sample solution matrix.

Zn (Zinc)

Typical Analysis
Refer to calcium in chicken blood plasma.

Sample Preparation
Refer to calcium in chicken blood plasma.
Use the centrifuged solution; no further dilution is required (dilution factor 1/5).
For 2.2 μg/mL Zn, the solution concentration will be approximately 0.4 μg/mL Zn.

Standard Preparation
Refer to zinc standard conditions.
Prepare calibration standards containing 0, 0.3, 0.5, 1.0 μg/mL Zn.
Chemical

Sulfuric Acid

As (Arsenic)

Range
1–10 μg/mL As

Typical Analysis
H₂SO₄ 97.0%  As 0.001%

Interferences
At 193.7 nm, non-atomic species in the flame absorb strongly. Use a background corrector to check for the presence of background absorption.

Sample Preparation
Cautiously add 10 mL sulfuric acid sample to 15 mL water, using a pipette with filler bulb. Cool, dilute to 25 mL.

Standard Preparation
Refer to arsenic standard conditions.
Prepare a 10 μg/mL As solution.
Repeat the above sample preparation with the addition of 5 mL of 10 μg/mL As before dilution to 25 mL.
This procedure gives a standard addition of 2 μg/mL As in the sulfuric acid.
Further additions can be made in a similar manner to give standard addition solutions of 4 μg/mL and 6 μg/mL.

Organometallic Compounds

As (Arsenic)

Typical Analysis
As 34.0%
C, H and O remainder

Interferences
At 193.7 nm wavelength, non-atomic species in the flame absorb strongly. Use a background corrector to check for the presence of background absorption.

Sample Preparation
Dissolve 0.100 g of sample in 20 mL distilled water and 5 mL ethanol. Make up to 100 mL with distilled water.
Take 10 mL of prepared solution, add 5 mL ethanol and dilute to 100 mL with distilled water.
For 34.0% As, the dilute solution will contain approximately 35 μg/mL As.

Standard Preparation
Refer to arsenic standard conditions.
Prepare calibration standards containing 0, 20, 30, 40, 50 μg/mL As in 5% v/v ethanol.

Si (Silicon)

Typical Analysis
Si 11.0%
S, C and H remainder

Interferences
The method of standard additions is used to compensate for the sample matrix.

Sample Preparation
Dissolve 0.200 g of sample in methyl isobutyl ketone and make up to 100 mL with this solvent.
For 11.0% Si, the sample concentration will be approximately 220 μg/mL Si.

Standard Preparation
Dissolve 0.1190 g of a polydimethyl siloxane containing 37.8% Si in methyl isobutyl ketone. Make up to 100 mL with this solvent to give a solution containing 450 μg/mL Si.

NOTE
If the above type of silicon standard is not available, use a CONOSTAN® silicon standard and vary the standard weight accordingly to give a final solution concentration of 450 μg/mL Si.

* Registered trade mark of Continental Oil Company.
Methodology

Additions standards:
Take 20 mL aliquots of the sample solution, add 0, 5, 10, 20 mL of the 450 μg/mL silicon standard and make up to 100 mL with methyl isobutyl ketone.

The addition standards will contain 0, 22.5, 45, 90 μg/mL added silicon.

**Ti (Titanium)**

**Typical Analysis**

Ti  38.0%
S, C and H  remainder

**Interferences**

The method of standard additions is used to compensate for the sample matrix which depresses the titanium absorbance.

**Sample Preparation**

Dissolve 0.300 g sample in diisobutyl ketone (DIBK). Make up to 250 mL with this solvent.

For 38% Ti, the sample concentration will be approximately 460 μg/mL Ti.

**Standard Preparation**

Dissolve 1.8662 g of A.R. potassium titanyloxylate (13.53% Ti) in distilled water. Make up to 250 mL. The solution will contain 1000 μg/mL Ti.

Additions standards:
Take 25 mL aliquots of the sample solution, add 0, 5, 10, 20 mL of the 1000 μg/mL Ti standard and make up to 100 mL with distilled water.

The addition standards will contain 0, 50, 100, 200 μg/mL added titanium.

Prepare a blank solution by diluting 25 mL DIBK to 100 mL with distilled water.

**Organometallic ‘Soaps’**

**Co (Cobalt)**

**Range**

5–18% Co

**Typical Analysis**

12.5% Co

**Sample Preparation**

Dissolve 2.000 g of sample in metal-free kerosine; make up to 100 mL with the same solvent.

Dilute 1 mL of the prepared solution to 100 mL with kerosine. For 12.5% Co, the dilute solution will contain approximately 25 μg/mL Co.

**Standard Preparation**

Dissolve 0.287 g of cobalt cyclohexanecarboxylate (17.4% Co) in 10 mL xylene, 2 mL 2-ethyl-1-hexylamine and 2 mL 2-ethylhexanoic acid with gentle heating. Cool, dilute to 100 mL with kerosine to give a solution containing 500 μg/mL Co. Prepare calibration standards containing 0, 10, 20, 30, 40 μg/mL Co by dilution of the 500 μg/mL Co standard with kerosine.

**Cu (Copper)**

**Range**

4–12% Cu

**Typical Analysis**

6.9% Cu

**Sample Preparation**

Dissolve 2.000 g of sample in metal-free kerosine; make up to 100 mL with the same solvent.

Dilute 1 mL of the prepared solution to 100 mL with kerosine. For 6.9% Cu, the dilute solution will contain approximately 14 μg/mL Cu.

**Standard Preparation**

Dissolve 0.326 g of copper cyclohexanecarboxylate (15.8% Cu) in 5 mL kerosine and 5 mL 2-ethylhexanoic acid with gentle heating. Cool, dilute to 100 mL with kerosine to give a solution containing 500 μg/mL Cu. Prepare calibration standards containing 0, 10, 15, 20, 25 μg/mL Cu by dilution of the 500 μg/mL Cu solution with kerosine.

**Pb (Lead)**

**Range**

15–33% Pb
Typical Analysis
21.5% Pb

Sample Preparation
Dissolve 2.000 g of sample in metal-free kerosine; make up to 100 mL with the same solvent.

Dilute 1 mL of the prepared solution to 200 mL with kerosine. For 21.5% Pb, the dilute solution will contain approximately 22 μg/mL Pb.

Standard Preparation
Dissolve 0.1365 g of lead cyclohexanebutyrate (36.61% Pb) in 5 mL kerosine and 5 mL 2-ethylhexanoic acid with gentle heating. Cool, dilute to 100 mL with kerosine to give a solution containing 500 μg/mL Pb. Prepare calibration standards containing 0, 10, 15, 20, 25, 35 μg/mL Pb by dilution of the 500 μg/mL Pb solution with kerosine.

Organometallic Salts

Cd (Cadmium)

Range
0.5–15% Cd

Sample Preparation
Weigh out 0.500 g of the organic compound, dissolve it in xylene and dilute to 100 mL with xylene.

Dilute 2 mL of this solution to 100 mL with xylene.

For 15% Cd, the final solution concentration will be approximately 15 μg/mL Cd.

Standard Preparation
Dissolve 0.2084 g of cadmium cyclohexanebutyrate (24.0% Cd) in 2 mL xylene and 4 mL 2-ethylhexylamine with gentle heating. Cool and dilute to 100 mL with xylene to give a 500 μg/mL Cd stock solution.

Dilute aliquots of this solution with xylene to give standard solutions containing 0, 5, 10, 20 μg/mL Cd.

Pb (Lead)

Range
10–20% Pb

Sample Preparation
Refer to cadmium in organometallic salts.

For analysis, dilute 2 mL of the prepared solution to 100 mL with xylene. For 20.0% Pb, the dilute solution will contain approximately 20 μg/mL Pb.

Standard Preparation
Dissolve 0.1365 g of lead cyclohexanebutyrate (36.61% Pb) in 3 mL xylene and 5 mL 2-ethylhexanoic acid with gentle heating. Cool, dilute to 100 mL with xylene to give a solution containing 500 μg/mL Pb.

Prepare calibration standards containing 0, 10, 15, 20, 25 μg/mL Pb by dilution of the 500 μg/mL Pb solution with xylene.

Sn (Tin)

Range
Suitable for tin determination in hexanoic and octanoic acid metal salts (approximately 20% tin).

Sample Preparation
See cadmium in organometallic salts. Dilute the original sample solution 1:10 with xylene. For 20% Sn in the sample, this is 100 μg/mL Sn in solution.

Standard Preparation
Dissolve 0.431 g of dibutyltin bis(2-ethylhexanoate), 23.2% Sn, in 5 mL xylene with heating. Dilute to 100 mL with xylene to give 1000 μg/mL Sn.

Dilute aliquots of this solution with xylene to give 50, 100, 150, 200, 300 μg/mL Sn standards.

Zn (Zinc)

Range
Suitable for hexanoic and octanoic acid salts and other compounds soluble in xylene or other organic solvents.

Sample Preparation
Dissolve 0.500 g sample in xylene and dilute with xylene to 100 mL. Dilute 1 mL to 100 mL with xylene. For 10% Zn in a 0.500 g sample this is 5 μg/mL Zn in solution.
Standard Preparation

Dissolve 0.300 g of zinc cyclohexanebutyrate (16.66% Zn)* in 3 mL xylene and 5 mL 2-ethylhexanoic acid with slight heating. Dilute to 100 mL with xylene to give 500 μg/mL Zn. Prepare calibration standards of 0, 2.5, 5, 7.5 μg/mL Zn in xylene.

*This content may vary. Standards should be of certified metal content.

Organic Stabilizers

**Ba (Barium)**

Range

1–10% Ba

Typical Analysis

8.2% Ba

Interferences

Molecular species in the flame may absorb strongly. Molecular absorption is most common at wavelengths below about 350 nm. To check for non-atomic absorption at the barium wavelength use the following procedure. Since the deuterium lamp is not effective at the 553.6 nm line, an alternative source may be used, i.e., a molybdenum lamp at the nearby line of 553.3 nm can act as a continuum source to measure the non-atomic absorbance. The non-atomic signal is then subtracted from the apparent absorbance of the sample and standard solutions, as measured at the normal 553.6 nm barium line.

Barium is partially ionized in the nitrous oxide-acetylene flame. To suppress ionization add a sodium organometallic salt to give a final concentration of 1000 μg/mL sodium in all solutions.

Reagents

Organo-metallic sodium (10000 μg/mL Na). Dissolve about 9 g of sodium naphthylacetate in 6 mL 2-ethylhexanoic acid with gentle heating. Cool, dilute to 100 mL with 1:1 kerosine-butyloxitol to give a solution containing approximately 10000 μg/mL Na.

Sample Preparation

Dissolve 0.100 g of sample in 5 mL metal-free kerosine and 3 mL 2-ethylhexanoic acid with gentle heating. Cool, dilute to 100 mL with 10000 μg/mL sodium solution and dilute to 100 mL with 1:1 kerosine-butyloxitol.

For 8.2% Ba, the sample concentration will be approximately 80 μg/mL Ba.

Standard Preparation

Dissolve 0.172 g of barium cyclohexanebutyrate (29.1% Ba) in 5 mL metal-free kerosine and 3 mL 2-ethylhexanoic acid with gentle heating. Cool, dilute to 100 mL with kerosine to give a solution containing 500 μg/mL Ba.

Prepare calibration standards containing 0, 25, 50, 75, 100 μg/mL Ba. Add 10 mL 10000 μg/mL Na solution to each standard and dilute to 100 mL with 1:1 kerosine-butyloxitol.

Instrument Parameters

Refer to barium standard conditions.

Wavelength 553.6 nm

Fuel acetylene

Support nitrous oxide

**Cd (Cadmium)**

Range

0.5–5% Cd

Typical Analysis

0.95% Cd

Sample Preparation

Dissolve 0.100 g of sample in 5 mL metal-free kerosine and 3 mL 2-ethylhexanoic acid with gentle heating. Cool, dilute to 100 mL with kerosine.

Dilute 2 mL of the prepared solution to 100 mL with kerosine. For 0.95% Cd, the dilute solution will contain approximately 0.2 μg/mL Cd.
Methodology

**Standard Preparation**

Dissolve 0.2084 g of cadmium cyclohexanebutyrate (24.0% Cd) in 2 mL xylene and 4 mL 2-ethylhexylamine with gentle heating. Cool, dilute to 100 mL with metal-free kerosine to give a solution containing 500 μg/mL Cd.

Take 2 mL of the prepared solution, add 2 mL 2-ethylhexylamine and dilute to 100 mL with kerosine. The dilute standard will contain 10 μg/mL Cd.

Prepare calibration standards containing 0, 0.1, 0.2, 0.5, 1.0 μg/mL Cd by diluting the 10 μg/mL Cd standard with kerosine.

**Zn (Zinc)**

**Range**

0.5–4% Zn

**Typical Analysis**

2.7% Zn

**Sample Preparation**

Refer to cadmium in organic stabilizers.

Use the dilute solution; for 2.7% Zn, the dilute solution will contain approximately 0.5 μg/mL Zn.

**Standard Preparation**

Dissolve 0.300 g of zinc cyclohexanebutyrate (16.66% Zn) in 3 mL xylene and 5 mL 2-ethylhexanoic acid with gentle heating. Cool, dilute to 100 mL with metal-free kerosine to give a solution containing 500 μg/mL Zn. Take 2 mL of the prepared solution, add 2 mL 2-ethylhexanoic acid and dilute to 100 mL with kerosine.

The dilute standard will contain 10 μg/mL Zn. Prepare calibration standards containing 0, 0.2, 0.4, 0.6, 0.8 μg/mL Zn by diluting the 10 μg/mL Zn standard with kerosine.

**Organic Complex**

**Co (Cobalt)**

**Typical Analysis**

Co 10%

**Sample Preparation**

Digest 0.200 g of sample with 5 mL sulfuric acid and 5 mL nitric acid in a covered beaker. Boil until the solution clears and sulfur trioxide fumes are present. Remove the cover and fume down to an approximately volume of 2 mL. If carbonaceous matter precipitates, add another 1 mL nitric acid and refume. Cool, transfer to a 100 mL flask and make up to volume with distilled water. For 10% Co, the solution concentration will be approximately 200 μg/mL Co in 2% sulfuric acid.

**Standard Preparation**

Refer to cobalt standard conditions.

Prepare calibration standards containing 0, 100, 150, 200, 250 μg/mL Co in 2% sulfuric acid.
**Methodology**

**Food**

**Beer**

**Fe (Iron)**

**Typical Analysis**

Fe 0.1 μg/mL

**Interferences**

Interference is experienced from the dissolved carbon dioxide causing irregular aspiration of the sample. This is overcome by degassing the sample prior to analysis. The viscosity levels of some beers can cause standardization problems and it is recommended that a standard addition technique be used.

Background correction is used to correct for non-atomic absorption.

**Sample Preparation**

De-gas the sample by pouring it into a beaker and stirring vigorously to ensure air entainment.

Dilute duplicate 25 mL aliquots of sample to 50 mL, with the addition of 0.5 mL of a 10 μg/mL Fe solution to one of the aliquots.

**K (Potassium)**

**Typical Analysis**

K 400 μg/mL

**Sample Preparation**

Partially de-gas the sample by pouring it into a beaker and stirring vigorously. Dilute 1 mL sample to 500 mL.

For 400 μg/mL K, the solution concentration will be approximately 0.8 μg/mL K.

**Standard Preparation**

Refer to potassium standard conditions.

Prepare calibration standards containing 0, 0.5, 0.75, 1.0 μg/mL K.

**Na (Sodium)**

**Range**

Up to 300 μg/mL Na

**Typical Analysis**

Fe 0.1 μg/mL  K 700 μg/mL  Na 200 μg/mL

**Sample Preparation**

Refer to iron in beer. Dilute 25 mL beer to 50 mL.

For 200 μg/mL Na, the solution concentration will be approximately 100 μg/mL Na.

**Standard Preparation**

Refer to sodium standard conditions.

Prepare standards containing 0, 50, 100, 150 μg/mL Na, with the addition of 350 μg/mL K and an appropriate alcohol level to match the sample.

**Fish**

**Hg (Mercury)**

**Cold vapor technique**

**Interferences**

Various materials in the fish digest interfere, and the method of standard additions must therefore be used.

At 253.7 nm, non-atomic species in the sample may absorb strongly. Use a background corrector to check for the presence of background absorption.

**Sample Preparation**

Weigh 5.0 g of ground sample into a 250 mL digestion flask equipped with a ground glass joint. Add 25 mL concentrated sulfuric acid, 20 mL 1:1 nitric acid, 1 mL of 2% sodium molybdate solution and boiling chips.

Connect a water-cooled condenser (packed with 6 mm Raschig rings) to the digestion flask and reflux gently for 1 hour. Allow the flask to cool for 15 minutes then add 20 mL of 1:1 nitric acid/perchloric acid mixture through the condenser.

Turn off the cooling water and boil the mixture until white fumes appear in the flask. Continue heating for 10 minutes.
Cool the flask then cautiously add 10 mL of water through the condenser while swirling the flask. Boil the solution for 10 minutes. Remove from the heat then wash the condenser with three 15 mL portions of water.

Cool to room temperature, transfer the digest to a 100 mL volumetric flask and dilute to volume with distilled water.

1 \( \mu g/g \) Hg in fish corresponds to 0.05 \( \mu g/mL \) in the solution.

**Standard Preparation**

Refer to mercury standard conditions.

Prepare a stock solution containing 5 \( \mu g/mL \) Hg.

**Analysis**

Refer to the operation of the vapor generation accessory.

**References**

**Vegetable Oil**

**Fe (Iron)**

**Typical Analysis**

Fe \( 3.8 \mu g/g \)

Ni \( 17.0 \mu g/g \)

**Interferences**

The method of standard additions is used to compensate for the viscosity and surface tension of the sample matrix. Addition standards are obtained by adding known concentrations of an organometallic standard to replicate sample solutions.

An alternative is to add an organic compound with similar physical characteristics, such as glycerol, to the solution of the organometallic standard. The glycerol is added at a level which matches the viscosity of the oil sample. A range of calibration standards can thus be prepared in the usual manner.

**Sample Preparation**

Dissolve 10.0 g of oil sample in metal-free kerosine and dilute to 100 mL with the same solvent. For 3.8 \( \mu g/g \) Fe, the solution concentration will be approximately 0.4 \( \mu g/mL \) Fe (or 8 \( \mu g/20 \) mL aliquot).

**Note** A blank solution of the kerosine solvent is also prepared.

**Standard Preparation**

Prepare an organometallic standard containing approximately 200 \( \mu g/mL \) Fe. Dry about 0.5 g of ferric cyclohexane butyrate (9.9% Fe) at 110°C for one hour. Dissolve 0.2020 g of dried reagent in 5 mL metal-free kerosine and 2 mL 2-ethylhexanoic acid with gentle heating. Cool, make up to 100 mL with kerosine.

**Addition Standards**

Take 20 mL aliquots of the sample solution, add 0, 0.05, 0.1 mL of the 200 \( \mu g/mL \) Fe standard and dilute to 25 mL with kerosine.

The addition standards will contain 0, 10, 20 \( \mu g \) added iron.

**Ni (Nickel)**

**Typical Analysis**

Refer to iron in vegetable oil.

**Interferences**

Refer to iron in vegetable oil.

The method of standard additions is used to compensate for the viscosity and surface tension of the sample matrix.

**Sample Preparation**

Refer to iron in vegetable oil.

For 17.0 \( \mu g/g \) Ni, the solution concentration will be approximately 1.8 \( \mu g/mL \) Ni (or 36 \( \mu g/20 \) mL aliquot).
Standard Preparation
Prepare an organometallic standard containing approximately 450 μg/mL Ni. Dry about 0.5 g of nickel cyclohexane butyrate (14.6% Ni) over fresh phosphorous pentoxide in a desiccator for two hours. Dissolve 0.3080 g of the dried salt in 5 mL metal-free kerosine and 2 mL 2-ethylhexanoic acid with gentle heating. Cool, make up to volume with kerosine.

Addition Standards
Take 20 mL aliquots of the sample solution, add 0, 0.1, 0.2 mL of the 450 μg/mL Ni standard and dilute to 25 mL with kerosine. The addition standards will contain 0, 45, 90 μg added nickel.

Fatty Acids
Al (Aluminium)
Range
0.1–1.0 μg/g Al
Typical Analysis
Cu 0.07 μg/g Mn 0.02 μg/g
Zn 0.4 μg/g Fe 3.0 μg/g
Ni 0.04 μg/g Al 0.1 μg/g

Interferences
Aluminium is partially ionized in the nitrous oxide-acetylene flame. To suppress ionization, add potassium nitrate or chloride solution to give a final concentration of 2000 μg/mL potassium in all solutions including the blank.

Sample Preparation
Gently heat duplicate 100 g lots of sample in silica dishes until the fatty acid self-ignites. Allow to burn freely with no further application of heat.

Wet the carbonaceous residue with 2–3 mL sulfuric acid; heat to drive off excess acid and ignite at 650–700°C. Dissolve the residue in 10 mL 6 N hydrochloric acid, add 0.1 g potassium as nitrate and dilute to 50 mL. Prepare a reagent blank in the same manner.

For 0.1 μg/g Al, the solution concentration will be approximately 0.2 μg/mL Al.

Standard Preparation
Refer to aluminium standard conditions.
Prepare calibration standards containing 0, 0.2, 0.5, 1.0, 2.0 μg/mL Al and 2000 μg/mL potassium in 1 M hydrochloric acid.

Fe (Iron)
Typical Analysis
Refer to aluminium in fatty acids.

Sample Preparation
Refer to aluminium in fatty acids.

For 3.0 μg/g Fe, the solution concentration will be 6 μg/mL Fe.

Standard Preparation
Refer to iron standard conditions.

Prepare calibration standards containing 0, 5, 10, 15 μg/mL Fe. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain HCl 1 M.

Mn (Manganese)
Typical Analysis
Refer to aluminium in fatty acids.

Sample Preparation
Refer to aluminium in fatty acids.

For 0.5 μg/g Mn, the solution concentration will be approximately 0.04 μg/mL Mn.

Standard Preparation
Refer to manganese standard conditions.

Prepare calibration standards containing 0, 0.05, 0.1 μg/mL Mn. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

K 2000 μg/mL
HCl 1.2 N
**Methodology**

**Industrial**

**Carbon Deposits**

**Fe (Iron)**

**Range**
100–700 μg/g Fe

**Sample Preparation**
Digest 1.000 g of sample with 10 mL sulfuric and 5 mL nitric acid in a covered beaker. Boil until the solution clears and sulfur trioxide fumes are present. Remove the cover and fume down to an approximate volume of 2 mL.

If carbonaceous matter re-precipitates, add another 1 mL nitric acid and refume.

Cool, transfer to a 25 mL volumetric flask and make up to volume with distilled water. Prepare an analytical solution by further diluting 2 mL of the sample solution to 10 mL.

For 627 μg/g Fe, the analytical solution will contain approximately 5 μg/mL Fe.

**Standard Preparation**
Refer to iron standard conditions.

Prepare calibration standards containing 0, 2, 4, 6, 8 μg/mL Fe in 2% sulfuric acid.

**V (Vanadium)**

**Range**
30–50 μg/g V

**Sample Preparation**
Refer to iron in carbon deposit.

Use the original solution for analysis.

For 43 μg/g V, the solution concentration will be approximately 1.7 μg/mL V in 10% sulfuric acid.

**Standard Preparation**
Refer to vanadium standard conditions.

Prepare calibration standards containing 0, 1.0, 1.5, 2.0, 2.5 μg/mL V in 10% sulfuric acid.

**Cement**

**Al (Aluminium)**

**Range**
Suitable up to 3% Al₂O₃

**Typical Analysis**

\[
\begin{align*}
\text{SiO}_2 & \quad 25\% \\
\text{Fe}_2\text{O}_3 & \quad 3\% \\
\text{MgO} & \quad 1\% \\
\text{Na}_2\text{O} & \quad 0.2\% \\
\text{K}_2\text{O} & \quad 0.3\% \\
\text{Al}_2\text{O}_3 & \quad 3\%
\end{align*}
\]

**Interferences**

Sodium and calcium are ionized in the nitrous oxide-acetylene flame thus producing enhancement of aluminium absorbance.

Silicon depresses aluminium absorbance by the formation of a refractory complex.

These effects are overcome by using standards containing these and other major matrix elements at the same concentration as the sample.

**Sample Preparation**
Fuse 0.500 g sample with 2 g NaOH or Na₂O₂ in either a platinum or zirconium crucible, (Note 1).

Cool the melt and dissolve in 100 mL warm water. Acidify by the slow addition of 15 mL hydrochloric acid. Add 5 mL of 10 volume hydrogen peroxide and warm gently to a maximum temperature of 60°C. Dilute to 250 mL.

For 3% Al₂O₃, the solution concentration will be approximately 30 μg/mL Al.

Note 1: If a platinum crucible is used, do not raise the temperature above a dull red heat. Fusion for about 3 minutes is adequate.

**Standard Preparation**
Refer to aluminium standard conditions. Prepare calibration standards containing 0, 20, 30, 40 μg/mL Al. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above, the standards would contain:
Ca (Calcium)

Typical Analysis
Refer to aluminium in cement.

Interferences
At normal sample concentrations, silicon and aluminium depress the calcium absorbance by 50–70% and iron by 5–7%. These effects are overcome by using the nitrous oxide-acetylene flame.

The partial ionization of calcium in this flame is overcome by the excess sodium used in dissolution of the sample.

Sample Preparation
Refer to aluminium in cement.

Dilute a 25 mL aliquot of the sample solution to 50 mL. For 64% CaO, the final solution concentration will be approximately 450 μg/mL Ca.

Standard Preparation
Refer to calcium standard conditions.

Prepare calibration standards containing 0, 250, 500, 750 μg/mL Ca. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above, the standards would contain:

<table>
<thead>
<tr>
<th>Reagent</th>
<th>Concentration</th>
</tr>
</thead>
<tbody>
<tr>
<td>NaOH</td>
<td>0.8 g/100 mL</td>
</tr>
<tr>

</tr>
<tr>
<td>Fe</td>
<td>40 μg/mL</td>
</tr>
</tbody>
</table>

Mg (Magnesium)

Typical Analysis
Refer to aluminium in cement.

Interferences
Chemical interference from aluminium and silicon is overcome by the use of the nitrous oxide-acetylene flame.

Sample Preparation
Refer to aluminium in cement.

For 1% MgO, the solution concentration will be approximately 12 μg/mL Mg.

Standard Preparation
Refer to magnesium standard conditions.

Fe (Iron)

Typical Analysis
Refer to aluminium in cement.

Interferences
Interference can be expected from the high matrix levels present. The use of a nitrous oxide-acetylene flame is recommended to overcome this.

Sample Preparation
Refer to aluminium in cement.

For 3% Fe₂O₃, the solution concentration will be approximately 40 μg/mL Fe.

Standard Preparation
Refer to iron standard conditions.

Prepare calibration standards containing 0, 20, 40, 60 μg/mL Fe. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above, the standards would contain:

<table>
<thead>
<tr>
<th>Reagent</th>
<th>Concentration</th>
</tr>
</thead>
<tbody>
<tr>
<td>NaOH (or Na₂O₂)</td>
<td>0.8 g/100 mL</td>

<td>Si</td>
<td>115 μg/mL</td>
</tr>
<tr>
<td>Fe</td>
<td>20 μg/mL</td>
</tr>
</tbody>
</table>

Al ( Aluminium)

Typical Analysis
Refer to aluminium in cement.

Interferences
Chemical interference from aluminium and silicon is overcome by the use of the nitrous oxide-acetylene flame.

Sample Preparation
Refer to aluminium in cement.

For 1% Al₂O₃, the solution concentration will be approximately 20 μg/mL Al₂O₃.

Standard Preparation
Refer to aluminium standard conditions.
Prepare calibration standards containing 0, 15, 20, 25 μg/mL Mg. The standard solutions must contain the same reagents and major matrix elements at approximately the same concentration as the sample solutions. For example, in the typical case above the standards would contain:

<table>
<thead>
<tr>
<th>Element</th>
<th>Concentration</th>
</tr>

<tr>
<td>Si</td>
<td>230 μg/mL</td>
</tr>
<tr>
<td>HCl</td>
<td>0.6 mL/100 mL</td>
</tr>
<tr>
<td>NaOH</td>
<td>0.08 g/100 mL</td>
</tr>
</tbody>
</table>

Ni (Nickel)

Typical Analysis
Ni 100 μg/g    Cr 75 μg/g

Sample Preparation
Digest duplicate 1.000 g samples, dried and finely powdered, with 35 mL 1:1 hydrochloric acid for 10 minutes. Cool and transfer to 100 mL volumetric flasks (filtering is not necessary). To one flask add 5 mL 10 μg/mL Ni solution, and dilute both solutions to 100 mL.

Standard Preparation
Refer to nickel standard conditions.
Standard addition is used so that matrix matching is unnecessary.
Prepare 10 μg/mL Ni standard by dilution of the stock solution.

Si (Silicon)

Typical Analysis
Refer to aluminium in cement.

Sample Preparation
Refer to aluminium in cement.
For 25% SiO₂, the solution concentration will be approximately 230 μg/mL Si.

Standard Preparation
Refer to silicon standard conditions.

Prepare calibration standards containing 0, 200, 250, 300 μg/mL Si. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

<table>
<thead>
<tr>
<th>Element</th>
<th>Concentration</th>
</tr>

Ceramic Surfaces (Glazed)

Cd (Cadmium)

Sample Preparation
Refer to procedure recommended for lead extracted from glazed ceramic surfaces.

Standard Preparation
Prepare calibration standards containing 0, 0.2, 0.5, 1.0, 2.0 μg/mL Cd in 4% acetic acid.

Pb (Lead)

Sample Preparation
Wash the products submitted for testing with a non-ionic detergent, rinse with tap water and follow by distilled water. Fill each dried item with 4% acetic acid and allow to stand at room temperature (20°C) for 24 hours. Record the volume of the solvent and prevent evaporation by covering with a watch glass.

Standard Preparation
Prepare calibration standards containing 0, 2, 5, 10, 20 μg/mL Pb in 4% acetic acid.

Clay

Ca (Calcium)

Interferences
To overcome the inter-element interferences the nitrous oxide-acetylene flame was used. Addition of potassium (2000–5000 μg/mL) prevents the loss of sensitivity due to ionization.

Sample Preparation
Place 0.2000 g of dried sample (2 hours at 140°C) in a PTFE-lined pressure container (1). Add one drop each of hydrochloric and nitric acid, and then slowly add 4 mL of hydrofluoric acid. Seal the container and place in an oven at 125°C for two hours. Cool, open the container and transfer the solution to a platinum dish.

Add 5 mL of hydrofluoric acid and 5 mL of perchloric acid, heat to white fumes of perchloric acid. Then cool and add 2 mL of hydrochloric acid. Warm the sample to dissolve the salts.

Transfer to a plastic 50 mL volumetric flask, add potassium chloride to give a final concentration of 5000 μg/mL K and make up to volume with distilled water. For the sample with 0.1% CaO, the solution will contain 3 μg/mL Ca.

NOTE Wherever possible plastic laboratory ware should be substituted for normal glass. The prepared solution should be stored in a plastic bottle.

Standard Preparation
Prepare calibration standards containing 0, 1, 2, 4, 5 μg/mL Ca.

The standard solutions must contain the same reagents at approximately the same concentrations. For example, in the case above, the standards should contain:

- Al₂O₃: 310 μg/mL
- K: 5000 μg/mL
- HCl: 2 mL/50 mL
- HClO₄: 5 mL/50 mL

References

Mg (Magnesium)
Typical Sample
Flint Clay  SiO₂  43.6%  Al₂O₃  38.8%  MgO  0.15%  CaO  0.10%  SrO  0.18%

Interferences
Chemical interference from aluminium and silicon is overcome by the use of the nitrous oxide-acetylene flame.

Sample Preparation
Refer to the procedure recommended for calcium in clay. For the sample with 0.15% MgO, the solution will contain 3.68 μg/mL Mg.

Standard Preparation
Prepare calibration standards 0, 2, 5, 10 μg/mL Mg. The standard solution must contain the same reagents and major matrix elements of approximately the same concentrations as the sample solutions.

- SiO₂: 350 μg/mL
- Al₂O₃: 310 μg/mL
- K: 5000 μg/mL
- HCl: 2 mL/50 mL
- HClO₄: 5 mL/50 mL

Sr (Strontium)
Typical Range
Flint Clay  SiO₂  43.6%  Al₂O₃  38.8%  MgO  0.15%  CaO  0.10%  SrO  0.18%

Interferences
Chemical interference from aluminium and silicon is overcome by the use of the nitrous oxide-acetylene flame.

The ionization of strontium is suppressed by addition of potassium nitrate or chloride.
Sample Preparation
Refer to the procedure recommended for calcium in clay. For the sample containing 0.18% SrO, the solution will contain 7.9 μg/mL Sr.

Standard Preparation
Prepare calibration standards containing 0, 2, 5, 10 μg/mL Sr. Ensure that all standard solutions contain the same reagents and major matrix elements at approximately the same concentrations as the sample solutions.

For example, in a typical case above, standards would contain:

- SiO₂: 350 μg/mL
- Al₂O₃: 310 μg/mL
- K: 5000 μg/mL
- HCl: 2 mL/50 mL
- HClO₄: 5 mL/50 mL

Electroplating Solution

Cu (Copper)

Typical Analysis
Nickel solution (Watts type)
Nickel sulfate (NiSO₄·6H₂O) 30.0% w/w
Nickel chloride (NiCl₂·6H₂O) 5.2%
Boric acid 4.5%
Water 60.3%

Interferences
The method of standard additions is used to compensate for differences in sample viscosity and matrix effects.

Sample Preparation
Use the sample directly.

Standard Preparation
Make up 50 μg/mL Cu standard by taking 5 mL of 1000 μg/mL Cu standard and diluting to 100 mL with distilled water.
Pipette 10 mL aliquots of the sample solution into five 50 mL volumetric flasks.
Add 0, 1, 2, 5 mL of 50 μg/mL Cu standard and make up to volume with distilled water.

The addition standard will contain 0, 1, 2, 5 μg/mL added copper, respectively.

Fe (Iron)

Typical Analysis
Nickel solution (Watts type)
Nickel sulfate (NiSO₄·6H₂O) 30.0% w/w
Nickel chloride (NiCl₂·6H₂O) 5.2%
Boric acid 4.5%
Water 60.3%

Interferences
Matrix interferences are minimized by application of the standard addition method.

Sample Preparation
Use the sample directly.

Standard Preparation
Prepare 50 μg/mL Fe standard by diluting 5 mL of 1000 μg/mL Fe standard to 100 mL with distilled water.
Pipette 10 mL aliquots of the sample into four 50 mL volumetric flasks and add 0, 1, 2, 5 mL of 50 μg/mL Fe standard.
Make up to volume with distilled water.
The prepared standards will contain 0, 1, 2, 5 μg/mL added iron.

Pb (Lead)

Typical Analysis
Nickel solution (Watts type) same as for copper in electroplating solutions.

Interferences
Method of standard additions is used to compensate for the sample matrix.

Sample Preparation
Use the sample directly.

Standard Preparation
Dilute 5 mL of 1000 μg/mL Pb solution to 100 mL to obtain 50 μg/mL Pb standard.

Addition Standards
Pipette 10 mL aliquots of the sample solution into five 50 mL volumetric flasks.
Add 0, 1, 2, 5, 10 mL of 50 μg/mL Pb standard and make up to volume with distilled water. The prepared solutions will contain 0, 1, 2, 5, 10 μg/mL added lead.

Zn (Zinc)

Typical Analysis
Nickel solution (Watts type) same as for copper in electroplating solutions.

Interferences
Interferences due to matrix effect are minimized by application of the standard addition method.

Sample Preparation
Prepare 10 μg/mL Zn standard by diluting 1 mL of 1000 μg/mL Zn standard to 100 mL.

Addition Standards
Pipette 10 mL aliquots of the solution into five 50 mL volumetric flasks. Add 0, 1, 2, 5, 10 mL of 10 μg/mL Zn standard and make up to volume with distilled water.

The prepared standards will contain 0, 0.2, 0.4, 1.0, 2.0 μg/mL.

Polymers

Ba (Barium)

Typical Range
0–0.1%

Interferences
Barium is partially ionized in the nitrous oxide-acetylene flame. To suppress ionization add potassium chloride to give a final concentration of 5000 μg/mL potassium in solution.

Standard Preparation
Refer to preparation recommended for cadmium in polymers.

Sample Preparation
Two sets of calibration standards are required for this determination:

- 0–40 μg/mL Ba in dilute H₂SO₄
- 0–40 μg/mL Ba in EDTA/NaOH solution.

Add 5000 μg/mL potassium as ionization suppressant to the acid solutions.

Presence of sodium from NaOH will suppress the ionization of barium in the second set of solutions.

Concentrations of reagents and major matrix components in both sets should be matched.

Ca (Calcium)

Typical Range
0.01–0.2%

Interferences
Inter-element interference is overcome by using a nitrous oxide-acetylene flame. Calcium is partially ionized in this flame. To suppress ionization add potassium chloride to give a final concentration of 5000 μg/mL potassium in all solutions including the blank.

Standard Preparation
Follow the preparation recommended for cadmium in polymers.

Sample Preparation
Prepare two sets of calibrations:

- 0–6.0 μg/mL Ca in dilute H₂SO₄
- 0–6.0 μg/mL Ca in EDTA/NaOH.

The concentrations of reagents and major matrix components in the standard should be matched with sample solutions in both sets.

Add equivalent of 5000 μg/mL potassium to all acid solutions including the blank. The solutions containing sodium hydroxide will not require additional ionization suppressant.

Cd (Cadmium)

This method is applicable to most polymeric materials such as polyvinyl chloride, polyethylene, polypropylene, ABS, polymethyl methacrylate, polyester, rubbers and nylon.

It is unsuitable for compositions highly filled with carbon black and for polytetrafluoroethylene.

Typical Range
0.01–0.10%
Standard Preparation

Weigh accurately 2.000 g of polymer cut into small pieces and place in a 200 mL conical flask. Slowly add 10 mL of concentrated sulfuric acid, cover with a watch glass and heat until charring is well progressed.

Allow to cool and add, dropwise, sufficient hydrogen peroxide (100 vols) to oxidize the charred matter and heat again. Cool, and repeat addition of hydrogen peroxide until solution remains colorless. Heat to white fumes of sulfuric acid, but do not try to greatly reduce the acid volume.

If solution is clear, add 20 mL of distilled water to the cool digestion mixture and transfer to a 100 mL volumetric flask and make up to volume. The solution prepared from a sample with 0.01% Cd will contain 2 μg/mL Cd.

For digestion with precipitate follow an alternative procedure.

Cool the digestion mixture and add 20 mL of distilled water. Swirl for ten minutes, cool and filter through a Whatman 42 paper.

Acid solution

Wash the precipitate with distilled water collecting the filtrate and the subsequent washings in a 100 mL volumetric flask. Make up to volume with distilled water.

Alkaline solution

Place the funnel with the filter paper and the precipitate in the neck of a 50 mL volumetric flask. Dissolve the precipitate by washing the paper with 20% sodium hydroxide solution saturated with EDTA. Follow by distilled water washings and make up to volume.

Sample Preparation

Prepare calibration solutions containing 0, 1.0, 2.0, 2.5 μg/mL Cd using similar acid concentrations as in the sample solution. Each standard solution should also contain the same major matrix elements as the sample at approximately the same concentrations.

Notes

- Care must be taken in handling hydrogen peroxide. Ensure that the volume of sulfuric acid is not greatly reduced by evaporation — 4 mL is the lower limit.
- Excessive charring during digestion must be avoided, as formed carbon will be very difficult to oxidize.
- If titanium is present in the sample the color of the solution will vary from light yellow to dark reddish-brown, due to the formation of titanium complexes of H₂O₂ in sulfuric acid.

References

Pb (Lead)

Typical Range

0.1–1.5%

Interferences

No interferences have been reported.

Standard Preparation

Follow the digestion procedure recommended for cadmium in polymers.

Sample Preparation

Prepare two sets of calibration solutions:

- 5–25 μg/mL Pb in dilute H₂SO₄
- 5–25 μg/mL Pb in EDTA/NaOH.

The concentrations of reagents and major matrix components in the standards should be matched with sample solutions in both sets.

Sb (Antimony)

Typical Range

0.05–0.5%

Standard Preparation

Refer to cadmium in polymers. For a sample with 0.5% Sb the solution will contain 100 μg/mL Sb.
Methodology

Sample Preparation
Prepare calibration solutions containing 0, 50, 80, 100, 150 μg/mL Sb. Ensure presence of the same quantities of reagents and major matrix elements as in the sample solution.

PVC

Sn (Tin)

Typical Analysis
PVC  97%   Sn  0.02%   Zn  0.02%
Ca  0.01%   Ti  2.0%

Interferences
At 224.6 nm, non-atomic species may absorb even in the nitrous oxide-acetylene flame. Use a background corrector to check for the presence of non-atomic absorption.

Standard Preparation
Boil a 2.000 g sample to dryness with 20 mL nitric acid. Cool and repeat once.
Cool and add a further 20 mL nitric acid and 4 mL perchloric acid. Heat until white perchlorate fumes appear, then cool the solution.

WARNING
Explosion Hazard
DO NOT ALLOW TO BOIL DRY; organic perchlorates are explosive and death, or serious injury may result. Refer to the warning on Page 3 of this book.

Repeat the fuming with 10 mL nitric acid and 4 mL perchloric acid until a clear solution results. Now heat to evaporate all the acid, leaving only a fine white residue.
Wash the residue into a PTFE beaker. Add 8 mL nitric acid and 4 mL hydrofluoric acid, and warm gently for one hour to complete the dissolution. Dilute to 25 mL in a plastic volumetric flask. For 0.02% Sn in the sample, the solution concentration will be 16 μg/mL.

Sample Preparation
Refer tin standard conditions.
Prepare standards containing 0, 10, 20, 30 μg/mL Sn.

Each standard solution must contain all the reagents and major matrix elements as the sample at approximately the same concentrations. For the typical sample above, standards should contain:

<table>
<thead>
<tr>
<th>Element</th>
<th>Concentration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ti</td>
<td>1500 μg/mL</td>
</tr>
<tr>
<td>Zn</td>
<td>15 μg/mL</td>
</tr>
<tr>
<td>Ca</td>
<td>10 μg/mL</td>
</tr>
<tr>
<td>HNO₃</td>
<td>30%</td>
</tr>
<tr>
<td>HF</td>
<td>15%</td>
</tr>
</tbody>
</table>

Ti (Titanium)

Typical Analysis
Refer to tin in PVC.

Standard Preparation
Refer to tin in PVC. For 2.0% Ti in a 2.000 g sample, the solution contains 1600 μg/mL Ti. Few samples are expected to exceed this concentration.

Sample Preparation
Refer titanium standard conditions.
Prepare calibration standards containing 1000, 1300, 1600 μg/mL Ti. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

<table>
<thead>
<tr>
<th>Element</th>
<th>Concentration</th>
</tr>
</thead>
<tbody>
<tr>
<td>HNO₃</td>
<td>30%</td>
</tr>
<tr>
<td>HF</td>
<td>15%</td>
</tr>
<tr>
<td>Zn</td>
<td>15 μg/mL</td>
</tr>
<tr>
<td>Ca</td>
<td>10 μg/mL</td>
</tr>
<tr>
<td>Sn</td>
<td>16 μg/mL</td>
</tr>
</tbody>
</table>

Zn (Zinc)

Typical Analysis
Refer to tin in PVC.

Standard Preparation
Refer to tin in PVC.
Dilute 5 mL sample to 100 mL.
For 0.02% Zn, the sample concentration will be 0.8 μg/mL.
Sample Preparation
Refer to zinc standard conditions.
Prepare calibration standards of 0, 0.5, 1.0, 1.5 \( \mu \)g/mL Zn in water.

Talc

As (Arsenic)

Vapor Generation Technique
At low concentrations, this element can be determined by the vapor generation technique. Details of the appropriate procedures are given in the operation manual supplied with the Agilent vapor generation accessory.

Standard Preparation
Refer to arsenic in water.

Range
50–500 ng arsenic
0.1–1.0 \( \mu \)g/g arsenic under the conditions of the given method. The analytical range can be varied by using different sample weights.

Typical Analysis
0.16 \( \mu \)g/g arsenic in cosmetic grade talc.

Interferences
Chemical interferences can be encountered in the generation of arsine. Oxidizing agents can prevent the reaction entirely. Excess nitric acid in particular must be absent from the test solution. Metals such as copper, which form a precipitate with potassium iodide, cannot be tolerated in large excess.

Sample Preparation
Suspend 2.500 g of finely ground talc sample in 50 mL hydrochloric-sulfuric acid mixture. Add excess potassium iodide to reduce the arsenic (approximately 0.5 g). Stir well and add 20% stannous chloride solution dropwise to clear the precipitated iodine. Stand for 45 minutes with frequent stirring; if necessary, repeat the addition of 20% stannous chloride to ensure complete reaction.

Filter through a fine paper (Whatman No. 542) to remove the suspended talc; wash with hydrochloric-sulfuric acid (50% v/v). Using normal filtration techniques, recycle the filtrate until it is clear. Transfer to a 100 mL volumetric flask and make up to volume with hydrochloric-sulfuric acid to give a solution with 50% v/v acid concentration.

Take 20 mL aliquots of the prepared solution for analysis. For 0.16 \( \mu \)g/g arsenic the analytical solution will contain approximately 80 ng arsenic.

Calcite

As (Arsenic)

Vapor Generation Technique
At low concentrations, this element can be determined by the vapor generation technique. Details of the appropriate procedures are given in the operation manual supplied with the Agilent vapor generation accessory.

Range
50–500 ng arsenic.
0.2–4.0 \( \mu \)g/g arsenic, depending upon analytical conditions.
Typical Analysis

0.25 μg/g arsenic in pharmaceutical grade calcite.

Interferences

Refer to arsenic in talc.

Sample Preparation

Dissolve 1.250 g of calcite in a minimum volume of concentrated hydrochloric acid. Add 20 mL hydrochloric-sulfuric acid (50% v/v). Add potassium iodide in excess (approximately 0.5 g) to reduce the arsenic. Stir well and add 20% stannous chloride solution dropwise to clear the liberated iodine. Allow to stand for 45 minutes with frequent stirring; if necessary add a few more drops of 20% stannous chloride to ensure that excess reductant is present. Transfer to a 100 mL volumetric flask and make up to volume with hydrochloric-sulfuric acid (50% v/v).

To extend the linear analytical range to 0.4–4.0 μg/g arsenic; dilute the prepared solution 1:1 with hydrochloric-sulfuric acid and take 20 mL aliquots of the diluted solution.

Standard Preparation

Refer to arsenic standard solutions.

Prepare a standard containing 0.5 μg/mL arsenic in 2% hydrochloric acid.

Prepare calibration standards containing 0, 50, 100, 200, 300, 400, 500 ng arsenic in 20 mL aliquots with a total acid concentration of 50% v/v (refer to arsenic in talc).

Kaolin

As (Arsenic)

Vapor Generation Technique

At low concentrations, this element can be determined by the vapor generation technique. Details of the appropriate procedures are given in the operation manual supplied with the Agilent vapor generation accessory.
Mineral

Fluorspar

Ba (Barium)

Typical Analysis

\[ \text{CaF}_2 \quad 98\% \quad \text{Ba} \quad 0.04\% \]

Interferences

Fluoride must be removed from the sample during the fuming step to prevent precipitation of insoluble barium fluoride.

Sample Preparation

Dissolve 0.500 g of fluorspar in 3 mL hydrochloric acid and fume to dryness twice. Cool, add 2 mL perchloric acid and heat to fumes. Cool, add 2 mL hydrofluoric acid and heat to fumes of perchloric acid appear. Cool, dissolve in water and dilute to 100 mL with the addition of 10 mL of 20000 μg/mL potassium as ionization suppressant. For 0.04% Ba, the solution concentration will be approximately 2 μg/mL Ba.

Standard Preparation

Refer to barium standard conditions.

Prepare calibration standards containing 0, 1, 2, 3 μg/mL Ba. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Ca 2500 μg/mL
- K 2000 μg/mL

Gypsum

Ca (Calcium)

Typical Analysis

Ca 25%   SO₄ 56%

Interferences

Sulfate ion depresses the calcium absorbance by 30%. This effect is overcome readily in a nitrous oxide-acetylene flame. Calcium is partially ionized in this flame. To suppress ionization, add potassium nitrate or chloride to give a final concentration of 2000 μg/mL potassium in all solutions including the blank.

Sample Preparation

Dissolve 1.000 g sample in 20 mL of 1:1 hydrochloric acid. Cool and dilute to 100 mL. Dilute a 1 mL aliquot of the sample solution to 100 mL with the addition of 2000 μg/mL potassium. For 25% Ca, the final solution concentration will be approximately 25 μg/mL Ca.

Standard Preparation

Refer to calcium standard conditions.

Prepare calibration standards containing 0, 20, 25, 30 μg/mL Ca. Each solution must contain 2000 μg/mL potassium.

Kyanite

Al (Aluminium)

Range

15-25% Al

Typical Analysis

Al 24%   Si 22%   Fe 0.1%

Interferences

Silicon depresses aluminium absorbance by the formation of a refractory complex. This is overcome by using standards containing silicon at the same concentration as the sample.

Sample Preparation

Fuse 1.000 g finely ground ore with 2.5 g NaOH pellets in a zirconium crucible.
Cool the melt and dissolve in warm water. Add 20 mL of 1:1 hydrochloric acid and heat gently with the slow addition of 30 volume hydrogen peroxide until the solution clears. To prevent hydrolysis of the silicon do not heat above 60°C. Dilute to 500 mL. For 24% Al the solution concentration will be approximately 480 μg/mL Al.

**Standard Preparation**

Refer to aluminium standard conditions. Prepare calibration standards containing 0, 300, 400, 500 μg/mL Al.

The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above, the standards would contain:

- **Si**: 450 μg/mL
- **Na**: 3000 μg/mL
- **HCl (1:1)**: 4 mL/100 mL

**Fe (Iron)**

**Typical Analysis**

Refer to aluminium in kyanite ore.

**Interferences**

The high levels of aluminium and silicon have been found to cause a slight depression of iron absorbance and it is necessary to match standards and samples for matrix levels.

**Sample Preparation**

Refer to aluminium in kyanite ore.

For 0.1% Fe, the solution concentration will be approximately 2 μg/mL Fe.

**Standard Preparation**

Refer to iron standard conditions. Prepare calibration standards containing 0, 1, 2, 3 μg/mL Fe. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- **Na**: 3000 μg/mL
- **Al**: 500 μg/mL
- **HCl (1:1)**: 4 mL/100 mL

**Si (Silicon)**

**Typical Analysis**

Refer to aluminium in kyanite ore.

**Sample Preparation**

Refer to aluminium in kyanite ore.

For 22% Si, the solution concentration will be approximately 440 μg/mL Si.

**Standard Preparation**

Prepare calibration standards containing 0, 200, 400, 600 μg/mL Si. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- **Na**: 3000 μg/mL
- **Al**: 500 μg/mL
- **HCl (1:1)**: 4 mL/100 mL

**Petalite**

**Li (Lithium)**

**Typical Analysis**

<table>
<thead>
<tr>
<th>Li₂O</th>
<th>SiO₂</th>
<th>Al₂O₃</th>
</tr>
</thead>
<tbody>
<tr>
<td>4%</td>
<td>75%</td>
<td>15%</td>
</tr>
</tbody>
</table>

**Sample Preparation**

Fuse 0.5 g finely ground sample with 2 g potassium hydroxide in a zirconium crucible at dull red heat for 15 minutes, and allow to cool. Dissolve the cake in 200 mL water, 10 mL hydrochloric acid and 5 mL 10 volume hydrogen peroxide. Dilute to 500 mL.

For 4% Li₂O in sample, solution concentration will be approximately 20 μg/mL.

**Standard Preparation**

Refer lithium standard conditions.
Prepare calibration standards containing 0, 10, 20, 30 μg/mL. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- **KOH**: 2 g/500 mL
- **HCl**: 10 mL/500 mL
- **SiO₂**: 0.375 g/500 mL
- **Al₂O₃**: 0.075 g/500 mL

fused and treated as for the sample.

**Quartz**

**Ti (Titanium)**

**Typical Analysis**

Ti 0.014%

**Interferences**

The method of standard additions is used to compensate for matrix effects.

**Sample Preparation**

Digest replicate 2 g samples with 10 mL of hydrofluoric acid and 5 mL nitric acid in PTFE beakers. Evaporate to approximately 2 mL to remove excess silicon. Cool, add 4 mL hydrofluoric acid and 1 g boric acid. Transfer to 50 mL volumetric flasks.

To one of the solutions add 2 mL of 100 μg/mL Ti standard and make up to volume with distilled water to give an addition standard containing 4 μg/mL Ti.

Further additions can be made in a similar manner to give standard addition solutions containing 8 μg/mL and 12 μg/mL Ti. For 0.014% Ti, the original sample solution will contain approximately 6 μg/mL Ti.

**Lead Concentrate**

**Cu (Copper)**

**Typical Analysis**

Cu 5%  Pb 55%  Zn 20%

**Sample Preparation**

Dissolve 0.100 g of ore in 5 mL of perchloric acid. Heat to perchloric fumes to remove sulfur. After the sulfur has evaporated, cool the solution and dilute to 100 mL. Dilute 10 mL of this solution to 100 mL.

For 5% Cu, the solution concentration will be approximately 5 μg/mL Cu.
**Methodology**

**Standard Preparation**

Refer to copper standard conditions.

Prepare calibration standards containing 0, 1, 2, 5 μg/mL Cu. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Pb  55 μg/mL
- Zn  20 μg/mL

**Tantalite Ore**

**Nb (Niobium)**

**Typical Analysis (Ore Concentrate)**

Ta₂O₅  50%  TiO₂  2%  Nb₂O₅  10%  SnO₂  15%

**Sample Preparation**

Fuse 1.000 g sample with 3 g sodium hydroxide in zirconium crucible at dull red heat until a clear melt is obtained. Cool and disperse the cake in 100 mL water in a PTFE beaker. Add 5 mL hydrochloric acid and 4 mL hydrofluoric acid, warm and add 4 mL 10 volume hydrogen peroxide to clear the solution. Cool the solution and dilute to 200 mL in a plastic flask. For 10% Nb₂O₅, the solution concentration will be approximately 350 μg/mL Nb.

**Standard Preparation**

Refer to niobium standard conditions.

Prepare calibration standards containing 0, 250, 500, 750 μg/mL Nb. The standard solutions must contain the same reagents and major matrix elements as the sample at approximately the same concentrations. For the typical sample above, each standard should contain:

- Ta  2000 μg/mL
- Nb  350 μg/mL
- NaOH  1.5 g/100 mL
- HCl  2.5 mL/100 mL
- HF  2 mL/100 mL

**Sn (Tin)**

**Typical Analysis**

Refer to niobium in tantalite ore.

**Sample Preparation**

Refer to niobium in tantalite ore.

For 15% SnO₂, the solution concentration will be approximately 600 μg/mL.

**Standard Preparation**

Refer to tin standard conditions.

Prepare standards containing 0, 200, 400, 600, 800 μg/mL Sn.

Each standard solution must contain the same reagents and major matrix elements as the sample at approximately the same concentrations. For the typical sample above, each standard should contain:

- Ta  2000 μg/mL
- Nb  350 μg/mL
- SnO₂  800 μg/mL
- NaOH  1.5 g/100 mL
- HCl  2.5 mL/100 mL
- HF  2 mL/100 mL

**Ta (Tantalum)**

**Typical Analysis**

Refer to niobium in tantalite ore.

**Interferences**

Sodium and fluoride at high concentrations are found in the sample solution and must be matched in the standards.

**Sample Preparation**

Refer to niobium in tantalite ore concentrate. Dilute 25 mL of sample solution to 50 mL.

For 50% Ta₂O₅, the solution concentration will be approximately 1000 μg/mL Ta.

**Standard Preparation**

Refer tantalum standard conditions.
Prepare calibration standards containing 500, 1000, 1500 μg/mL Ta. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Nb₂O₅ 250 μg/mL
- SnO₂ 400 μg/mL
- NaOH 0.75 g/100 mL
- HCl 1.2 mL/100 mL
- HF 1 mL/100 mL

**Ti (Titanium)**

**Typical Analysis (Ore Concentrate)**

Refer to niobium in tantalite ore.

**Sample Preparation**

Refer to niobium in tantalite ore. For 2% TiO₂ in a 1.000 g sample the solution concentration will be 60 μg/mL Ti.

**Standard Preparation**

Prepare calibration standards containing 0, 25, 50, 75 μg/mL Ti. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Ta₂O₅ 2500 μg/mL
- Nb₂O₅ 500 μg/mL
- SnO₂ 800 μg/mL
- NaOH 1.5 g/100 mL
- HCl 2.5 mL/100 mL
- HF 2 mL/100 mL

**Wolframite**

**W (Tungsten)**

**Typical Analysis**

WO₃ 65% SiO₂ remainder MnO₂ trace

**Sample Preparation**

Fuse 0.500 g samples with 3 g potassium hydroxide in zirconium crucibles at dull red heat until a clear melt is obtained. Dissolve the cake in 200 mL boiling water. Add 20 mL phosphoric acid, warm slightly and add 5 mL 10 volume hydrogen peroxide to oxidize any insoluble manganese salts. Cool and dilute to 500 mL.

For 65% WO₃, the sample concentration will be approximately 515 μg/mL W.

**Standard Preparation**

Refer tungsten standard conditions.

Prepare calibration standards containing 0, 250, 500, 750 μg/mL W. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- SiO₂ 0.16 g/500 mL
- KOH 3 g/500 mL
- H₃PO₄ 20 mL/500 mL

prepared as for the samples.

**Ferro-Manganese Slags**

**Ba (Barium)**

**Typical Analysis**

Al₂O₃ 15% SiO₂ 25%
FeO 1% Mn 35%
MgO 2% Na₂O + K₂O 2%
TiO₂ 0.5% BaO 5%

**Sample Preparation**

Dissolve 2.000 g of finely powdered ore in 20 mL water and 40 mL hydrochloric acid. Filter into a 200 mL flask, ignite the filter in a platinum crucible with 3 g of sodium carbonate. Dissolve the melt in 15 mL hydrochloric acid and 5 mL 3% hydrogen peroxide and dilute to 200 mL.

Add 20 mL of 10000 μg/mL sodium solution (as an ionization suppressant) to 5 mL of the solution and dilute to 100 mL.

For 5% BaO, the solution concentration will be approximately 23 μg/mL Ba.
**Methodology**

**Standard Preparation**
Refer to barium standard conditions.
Prepare calibration standards containing 0, 10, 20, 30 μg/mL Ba. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- **Al** 40 μg/mL
- **Si** 60 μg/mL
- **Mn** 150 μg/mL
- **Na₂CO₃** 0.07 g/100 mL
- **HCl** 1.8 mL/100 mL

**Fe (Iron)**

**Typical Analysis**
Refer to barium in ferro-manganese slags.

**Interferences**
The high levels of aluminium, silicon and manganese present have been found to depress the iron absorbance. The use of a nitrous oxide-acetylene flame has been found useful in preventing this interference.

**Sample Preparation**
Refer to barium in ferro-manganese slags. Use the undiluted solution.
For 1% FeO, the solution concentration will be approximately 77 μg/mL Fe.

**Standard Preparation**
Refer to iron standard conditions.
Prepare calibration standard solutions containing 0, 50, 100, 150 μg/mL Fe. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- **Al** 40 μg/mL
- **Si** 60 μg/mL
- **Mn** 150 μg/mL
- **Na₂CO₃** 0.07 g/100 mL
- **HCl** 1.8 mL/100 mL

**Ba** 50 μg/mL
**HCl** 27 mL/100 mL

**Mg (Magnesium)**

**Typical Analysis**
Refer to barium in ferro-manganese slags.

**Sample Preparation**
Refer to barium in ferro-manganese slags.
For 2% MgO, the solution concentration will be approximately 6 μg/mL Mg.

**Standard Preparation**
Refer to magnesium standard conditions.
Prepare calibration standards containing 0, 5, 10, 15 μg/mL Mg. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- **Al** 40 μg/mL
- **Si** 60 μg/mL
- **Mn** 150 μg/mL
- **Na₂CO₃** 0.07 g/100 mL
- **HCl** 1.8 mL/100 mL

**Antimony Ore**

**Hg (Mercury)**

**Range**
Up to 0.5% in antimony ore concentrates.

**Sample Preparation**
Accurately weigh 1,000 g of finely ground ore into a 250 mL conical beaker and slowly add 5 mL of 40% v/v bromine in carbon tetrachloride. Allow the solution to stand for 10 minutes after the initial vigorous reaction has ceased. Add 5 mL of aqua regia (1:3, nitric acid:hydrochloric acid); allow the solution to stand for a further five minutes, then heat gently to drive off excess bromine.

Cool the solution, add 20 mL of 10% tartaric acid and warm gently for two minutes.
Cool, add 5 mL of hydrochloric acid and dilute to 100 mL.
For 0.5% Hg, the solution concentration will be approximately 50 μg/mL Hg.

**Standard Preparation**

Refer to mercury standard conditions.

Prepare calibration standards containing 0, 25, 50, 100 μg/mL Hg. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

2.5% tartaric acid  
5% hydrochloric acid

**Borax Ore**

**B (Boron)**

**Typical Analysis**

B 14%  Ca 20%  H₂O 20%  
Si 2%  Ti 0.01%

**Sample Preparation**

Weigh duplicate finely ground samples of 1.000 g into acid-washed conical beakers. Add 100 mL water and 5 mL hydrochloric acid to each beaker and maintain just below boiling for 1 hour. Cool and filter through a Whatman 546 filter paper into a 200 mL volumetric flask, wash the filter with water and make the filtrate up to volume.

The precipitate is dried, ashed carefully in a zirconium crucible, cooled, and fused with 2 g sodium hydroxide at a dull red heat until a clear melt is obtained. The crucible is cooled and 2 mL water added to start dissolving the melt. The crucible is then transferred to a 250 mL beaker and 50 mL water added to wash out the fused cake. The solution is heated slightly to disperse the cake, then cooled to room temperature and neutralized to pH 5 by the slow addition of dilute hydrochloric acid (1:3). Transfer to a 100 mL volumetric flask and make up to volume.

For 14% B, the solution concentration will be approximately 700 μg/mL B.

**Standard Preparation**

Refer to boron standard conditions.

Prepare standards containing 200, 600, 1000 μg/mL B.

**Si (Silicon)**

**Typical Analysis**

Refer to boron in borax ore.

**Sample Preparation**

Refer to boron in borax ore.

For 2% Si, the solution concentration will be approximately 200 μg/mL Si.

**Standard Preparation**

Refer to silicon standard conditions.

Prepare calibration standards containing 0, 100, 150, 200 μg/mL Si. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

Na 11500 μg/mL  
Ca 2000 μg/mL  
B 1400 μg/mL

**Chrome Ore**

**Cr (Chromium)**

**Typical Analysis**

Cr₂O₃ 54%  FeO 20%  
SiO₂ 4%

**Interferences**

The high level of iron present can lead to interferences which can be overcome by the use of a nitrous oxide-acetylene flame.

**Sample Preparation**

Fuse 0.500 g of finely ground dried sample with 2 g of Na₂O₂ in a zirconium crucible.

Cool, dissolve the fused melt in 70 mL of water, 5 mL nitric acid and 5 mL of 10 volume hydrogen peroxide.

Dilute to 100 mL.

Dilute 1.0 mL of this solution to 100 mL.
For 54% Cr₂O₃, the final solution concentration will be approximately 19 μg/mL Cr.

**Standard Preparation**

Prepare calibration standards containing 0, 15, 20, 25 μg/mL Cr. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Fe: 8 μg/mL
- Na₂O₂: 0.02 g/100 mL
- Nitric Acid: 0.05 mL/100 mL

**Fe (Iron)**

**Typical Analysis**

Refer to chromium in chrome ore.

**Interferences**

A high dilution ratio is used in the preparation of the sample solution to prevent interference from chromium in the presence of hydrochloric acid.

**Sample Preparation**

Refer to chromium in chrome ore.

Dilute 1 mL of sample solution to 100 mL.

For 20% FeO, the solution concentration will be approximately 8 μg/mL Fe.

**Gold Ore**

**Ag (Silver)**

**Typical Analysis**

Fe 12.3%  Zn 350 μg/g

Ag 0.22 oz/ton (6 μg/g)  Li 70 μg/g

**Sample Preparation**

Digest 1.500 g of finely ground ore with 5 mL hydrochloric acid, 5 mL nitric acid and 5 mL hydrofluoric acid in a PTFE beaker. When the solution has cleared, add 5 mL sulfuric acid and evaporate to low volume to remove the hydrofluoric. Cool, transfer to a 50 mL volumetric flask and make up to the mark with distilled water. For 6 μg/g Ag, the solution concentration will be approximately 0.2 μg/mL.Ag.

**Standard Preparation**

Refer to silver standard conditions.

Prepare calibration standards containing 0, 0.1, 0.2, 0.3, 0.5 μg/mL Ag. The standards must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration.

For example, in the typical case above the standards would contain 3700 μg/mL Fe.

**Au (Gold)**

**Range**

Down to 0.05 μg/g

**Interferences**

No interferences have been noted using this procedure.

**Sample Preparation**

Digest duplicate 2.5 g lots of finely powdered ore (+200 mesh) in 5 mL of hydrochloric acid. Add 3 mL nitric acid, and evaporate slowly to dryness. Add 15 mL hydrochloric acid and 40 mL hot water to each, and allow to cool.

To one sample add 1 mL of 5.0 μg/mL Au standard solution.

Add 5 mL hydrobromic acid to each solution and extract the gold bromide complex into 5 mL methyl isobutyl ketone.
**Standard Preparation**
Refer to gold standard conditions.
Prepare a gold solution of 5.0 μg/mL by 1:200 dilution of 1000 μg/mL standard.

**Fe (Iron)**

Typical Analysis
Refer to silver in gold ores.

Sample Preparation
Refer to silver in gold ore.
Dilute 5 mL of the prepared solution to 100 mL. For 12.3% Fe, the analytical solution will contain approximately 185 μg/mL Fe.

**Standard Preparation**
Refer to iron standard conditions.
Prepare calibration standards containing 0, 50, 100, 150, 200 μg/mL Fe. The standards must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain 185 μg/mL Fe.

**Li (Lithium)**

Typical Analysis
Refer to silver in gold ores.

Sample Preparation
Refer to silver in gold ores.
Use the prepared solution for analysis.
Dilute 5 mL of the prepared solution to 100 mL. For 70 μg/g Li, the sample concentration will be approximately 2 μg/mL Li.

**Standard Preparation**
Refer to lithium standard conditions.
Prepare calibration standards containing 0, 1, 2, 3, 4 μg/mL Li. The standards must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration.

For example, in the typical case above the standards would contain 3700 μg/mL Fe.

**Zn (Zinc)**

Typical Analysis
Refer to silver in gold ores.

Sample Preparation
Refer to silver in gold ores.
Dilute 5 mL of the prepared solution to 100 mL. For 350 μg/g Zn, the analytical solution will contain approximately 0.5 μg/mL Zn.

**Standard Preparation**
Refer to zinc standard conditions.
Prepare calibration standards containing 0, 0.2, 0.4, 0.6, 1.0 μg/mL Zn. The standards must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain 185 μg/mL Fe.

**Iron Ore**

Co (Cobalt)

Typical Analysis
Fe 60% Si 4% Co 0.001%

**Interferences**
The high iron level can lead to severe interference and a solvent extraction technique is used to remove the excess iron.

Sample Preparation
Digest 2.000 g of finely ground ore in 25 mL hydrochloric acid. Evaporate to dryness and redissolve in a minimum volume of 50% hydrochloric acid. Filter and wash the residue with a minimum volume of hot 20% hydrochloric acid and water. Ignite the residue and set aside for subsequent treatment.

Evaporate the filtrate to a paste and redissolve in 20 mL hydrochloric acid. Oxidize the solution by the dropwise addition of nitric acid. Wash the solution into a 100 mL separating funnel with hydrochloric acid. Add 50 mL isobutyl acetate and shake the mixture for 30 seconds. Run off the aqueous layer into a second separating funnel. Wash the organic layer with 5 mL of hydrochloric acid and add the washings to the second separating funnel. Repeat the above extraction using 30 mL isobutyl acetate and 5 mL hydrochloric acid wash.
Evaporate the combined aqueous layers and washings almost to dryness. Redissolve the paste in 5 mL 50% nitric acid (v/v). This is designated solution A.

Heat the ignition residue with 5 mL hydrofluoric acid and 2–3 drops sulfuric acid in order to eliminate the SiO₂.

Evaporate to dryness and fuse with 0.2 g sodium carbonate.

Extract the melt with 10% nitric acid and combine with solution A.

Transfer the combined aqueous solutions to a 25 mL volumetric flask and make up to volume.

For 0.001% Co, the solution concentration will be approximately 1 μg/mL Co.

NOTE All percentage dilutions of acids are v/v dilutions.

Standard Preparation
Refer to cobalt standard conditions.
Prepare calibration standards containing 0, 0.5, 1.0, 1.5 μg/mL Co. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Nitric acid: 10 mL/100 mL
- Na₂CO₃: 0.8 g/100 mL

Rutile and Zircon Ores

Al (Aluminium)

Range
Suitable for rutile and zircon sands down to 0.05% Al₂O₃.

Typical Analysis
Rutile

- Cr₂O₃: 0.13%
- V₂O₅: 0.7%
- ZrO₂: 0.68%
- SnO₂: 0.02%
- Al₂O₃: 1%
- Nb₂O₅: 0.2%
- TiO₂ and SiO₂: remainder.

Interferences
Silicon and titanium depress the aluminium absorbance by the formation of refractory complexes. This effect is overcome by using standards containing these elements at the same concentration as the sample.

Sample Preparation
Fuse a catchweight sample (0.5 g) with 2.5 g KOH pellets in a zirconium crucible. Cool the melt and dissolve in 70 mL hot water and 1 mL hydrofluoric acid. Add 15 mL 1:1 sulfuric acid and heat gently to ensure a clear solution. Dilute to 100 mL. For 1% Al₂O₃, the solution concentration will be approximately 3 μg/mL Al.

Standard Preparation
Refer to aluminium standard conditions.
Prepare calibration standards containing 0, 1, 3, 5, 10 μg/mL Al. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Si: 1500 μg/mL
- Ti: 3000 μg/mL
- H₂SO₄ (1:1): 15 mL/100 mL
- HF: 1 mL/100 mL
- KOH: 2.5 g/100 mL

Cr (Chromium)

Typical Analysis
Refer to aluminium in rutile and zircon ores.

Sample Preparation
Refer to aluminium in rutile and zircon ores.
For 0.13% Cr₂O₃, the solution concentration will be approximately 4.5 μg/mL Cr.

Standard Preparation
Refer to chromium standard conditions.
Prepare calibration standards containing 0, 5, 10, 15 μg/mL Cr. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

<table>
<thead>
<tr>
<th>Element</th>
<th>Concentration</th>

<tr>
<td>H₂SO₄ (1:1)</td>
<td>15 mL/100 mL</td>
</tr>
<tr>
<td>HF</td>
<td>1 mL/100 mL</td>
</tr>
<tr>
<td>KOH</td>
<td>2.5 g/100 mL</td>
</tr>
</tbody>
</table>

Sn (Tin)

Range

Suitable for ores and sands containing as little as 0.02% SnO₂.

Interferences

At 224.6 nm, non-atomic species may absorb even in the nitrous oxide-acetylene flame. Use a background corrector.

Sample Preparation

Refer to aluminium in rutile and zircon ores, but use 1.000 g samples.

For 0.02% SnO₂, the solution concentration will be approximately 1.5 μg/mL Sn.

Standard Preparation

Prepare standards containing 0, 1.0, 1.5, 2.0 μg/mL Sn.

Each standard solution must contain the same reagents and major matrix elements as the sample at approximately the same concentrations. For the typical sample above, each standards should contain:

<table>
<thead>
<tr>
<th>Element</th>
<th>Concentration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Si</td>
<td>3000 μg/mL</td>
</tr>
<tr>
<td>Ti</td>
<td>6000 μg/mL</td>

</tr>
<tr>
<td>H₂SO₄ (1:1)</td>
<td>15 mL/100 mL</td>
</tr>
<tr>
<td>HF</td>
<td>1 mL/100 mL</td>
</tr>
</tbody>
</table>

V (Vanadium)

Typical Analysis

Refer to aluminium in rutile and zircon ores.

Interferences

Titanium and silicon may interfere. Matrix matching is essential.

Sample Preparation

Refer to aluminium in rutile and zircon ores.

For 0.7% V₂O₅ in rutile, the solution concentration will be 10 μg/mL V.

Standard Preparation

Refer vanadium standard conditions.

Prepare calibration standards containing 0, 5, 10, 15, 20 μg/mL V. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

<table>
<thead>
<tr>
<th>Element</th>
<th>Concentration</th>
</tr>
</thead>
<tbody>
<tr>
<td>KOH</td>
<td>2.5 g/100 mL</td>
</tr>
<tr>
<td>H₂SO₄ (1:1)</td>
<td>15 mL/100 mL</td>
</tr>
<tr>
<td>HF</td>
<td>10 mL/100 mL</td>
</tr>
<tr>
<td>(if used for sample)</td>
<td>10% HF</td>
</tr>
</tbody>
</table>

Zr (Zirconium)

Typical Analysis

Refer to aluminium in rutile and zircon ores.

Interferences

Many elements interfere, especially titanium, silicon and acids. The effects are minimized with a more oxidizing flame.

Sample Preparation

Refer to aluminium in rutile and zircon ores, but use 1.000 g samples (as for tin). For 0.68% ZrO₂ in a 1.000 g sample, the solution concentration will be approximately 50 μg/mL Zr.

Standard Preparation

Refer zirconium standard conditions.
Prepare calibration standards containing 0, 25, 50, 75 μg/mL Zr. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Si: 3000 μg/mL
- Ti: 6000 μg/mL
- KOH: 2.5 g/100 mL
- H₂SO₄ (1:1): 15 mL/100 mL
- HF: 1 mL/100 mL

(for used for sample)

**Sulfide Ores**

**Cu (Copper)**

**Range**

0.05–0.25% Cu

**References**

**Sample Preparation**

Dissolve 1.000 g finely ground, dried sample by gently heating with 20 mL hydrochloric acid in a covered beaker; do not boil. Reduce the volume to about 10 mL; add 5 mL nitric acid and evaporate to moist salts. Add 5 mL of 1:1 hydrochloric acid and heat gently to dissolve the salts. Cool, transfer to a 100 mL volumetric flask and make up to volume with 10% w/v ammonium acetate to keep the lead in solution.

For 0.08% Cu, the solution concentration will be approximately 8 μg/mL Cu.

**Standard Preparation**

Refer to copper standard conditions.

Prepare calibration standards containing 0, 5, 10, 20, 25 μg/mL Cu. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration.

For example, in the typical case above the standards would contain:

- Pb: 450 μg/mL
- Zn: 700 μg/mL
- HCl (1:1): 5 mL/10 mL
- ammonium acetate: 10% w/v

**Pb (Lead)**

**Range**

2.0–20.0% Pb

**Sample Preparation**

Refer to copper in sulfide ores.

Take 2 mL of the prepared solution and add 5 mL of 1:1 hydrochloric acid. Dilute to 100 mL with 10% w/v ammonium acetate.

For 4.5% Pb, the dilute solution will contain approximately 9 μg/mL Pb.

**Standard Preparation**

Refer to lead standard conditions.

Prepare calibration standards containing 0, 5, 10, 20, 30, 40 μg/mL Pb. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration.

For example, in the typical case above the standards would contain:

- HCl (1:1): 5 mL/100 mL
- ammonium acetate: 10% w/v

**Sb (Antimony)**

**Typical Analysis**

15.5% Sb (Stibnite type ores)

**Reagents**

Bromine-carbon tetrachloride mixture (2:3):
Prepare a mixture of A.R. grade bromine and carbon tetrachloride by adding 60 mL carbon tetrachloride to 40 mL bromine.
Aqua regia (hydrochloric/nitric acid; 3:1): Prepare 100 mL of aqua regia by mixing 75 mL concentrated hydrochloric acid with 25 mL concentrated nitric acid.

Tartaric acid solution (10% w/v): Dissolve 10 g A.R. tartaric acid in 100 mL distilled water.

**Sample Preparation**

Dry a portion of finely ground sample at 110°C. Weigh 0.500 g dried sample into a covered beaker and add 10 mL bromine-carbon tetrachloride mixture. Allow to stand for 10 minutes with periodic swirling. Add 10 mL aqua regia and allow to stand for a further 10 minutes. With the beaker still covered, heat gently on a water bath to drive off excess bromine (1–1.5 hour). Do not evaporate to dryness. Add 20 mL tartaric acid solution (10% w/v) and heat for a further 2 minutes. Cool, transfer to a 100 mL volumetric flask and make up to volume with distilled water.

For analysis, add 10 mL of prepared solution to 10 mL of hydrochloric acid and dilute to 100 mL.

For 15.5% Sb, the analytical solution will contain approximately 78 μg/mL Sb.

**Standard Preparation**

Refer to antimony standard conditions. Prepare calibration standards containing 0, 50, 75, 100 μg/mL Sb.

The standard solutions must contain the same reagents and major elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- hydrochloric acid 10 mL/100 mL
- tartaric acid (10% w/v) 2 mL/100 mL

**Zn (Zinc)**

**Range**

6.5–15.0% Zn

**Sample Preparation**

Refer to copper in sulfide ores.

Take 2 mL of prepared solution and add 5 mL of 1:1 hydrochloric acid. Dilute to 100 mL with 10% w/v ammonium acetate. For 6.7% Zn the dilute solution will contain approximately 14 μg/mL Zn.

**Standard Preparation**

Refer to zinc standard conditions. Prepare calibration standards containing 0, 10, 20, 30 μg/mL Zn. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration.

For example, in the typical case above, the standards would contain:

- HCl (1:1) 5 mL/100 mL
- ammonium acetate 10% w/v

**Sn (Tin)**

**Range**

Suitable for levels near 0.1%.

**Typical Analysis**

- Sn 0.15%
- WO₃ 0.2%
- SiO₂ remainder

**Interferences**

At 224.6 nm, non-atomic species may absorb even in the nitrous oxide-acetylene flame. Use a background corrector to check for the presence of non-atomic absorption.

**Sample Preparation**

Fuse 1.000 g sample and 5 g sodium peroxide in a zirconium crucible at dull red heat until a clear melt is obtained.
Cool and dissolve in water in a PTFE beaker. Neutralize to pH 7 with nitric acid (added slowly). Add 4 mL hydrofluoric acid and 3 g boric acid and dilute to 100 mL in a plastic volumetric flask. For 0.15% Sn, this is 15 μg/mL Sn in solution.

**Standard Preparation**

Refer tin standard conditions.

Prepare calibration standards containing 0, 5, 10, 15 μg/mL Sn.

Each standard solution must contain the same reagents and major matrix elements as the sample at approximately the same concentrations. For the typical sample above, the standards should contain:

- Si: 4500 μg/mL
- Na: 30000 μg/mL
- HF: 4 mL/100 mL
- H₃BO₃: 3 g/100 mL

**W (Tungsten)**

**Typical Analysis**

Refer to tin in tin ores.

**Interferences**

SiO₂ is separated and standard additions are used to compensate for Ca interference.

**Sample Preparation**

Add 50 mL hydrochloric acid to 1.000 g samples and heat at 70 °C for 3 hours. Allow to stand overnight and evaporate down to 10 mL to remove excess acid. Cool and dilute to 100 mL. For 0.2% WO₃ in a 1.000 g sample, this is 16 μg/mL W in solution. A 20 mL aliquot contains approximately 320 μg W.

**Standard Preparation**

Refer tungsten standard conditions.

Stock 1000 μg/mL solution is required.
Metallurgy

Carbon Steels

Cu (Copper)

Typical Analysis

Cu 1%  Si 1%  Mn 1%  V 0.2%
Ni 0.1%  Ti 0.1%  Fe 90%  C, S remainder

Sample Preparation

Weigh 2.000 g of sample into a PTFE beaker, add 5 mL of nitric acid and warm slowly. Add 5 mL of hydrochloric acid dropwise with constant stirring until the reaction subsides. Heat to near boiling for half an hour and cool. Add 2 mL of hydrofluoric acid very slowly so that the temperature of the mix does not exceed 35–40 °C, and let stand for half an hour to dissolve silicon, titanium and vanadium.

Filter the solution to remove carbon. Ash the filter and the residue in a platinum crucible. Rinse the crucible with a few drops of hydrofluoric and hydrochloric acids and add to the filtrate.

Dilute to 200 mL in a plastic volumetric flask.

Dilute 10 mL of this solution to 100 mL.

For 1% Cu, the final solution concentration will be approximately 10 μg/mL.

Standard Preparation

Refer to copper standard conditions.

Prepare calibration standards containing 0, 5, 10, 15 μg/mL Cu. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

Fe 900 μg/mL

Ti (Titanium)

Typical Analysis

Refer to copper in carbon steels.

Sample Preparation

Refer to copper in carbon steels; use the undiluted sample solution which contains approximately 10 μg/mL Ti.

Standard Preparation

Refer to titanium standard conditions.

Prepare calibration standards containing 5, 10, 15 μg/mL Ti. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

Fe 1%

At this concentration the other interferences are suppressed.

Iron Alloy

Al (Aluminium)

Typical Analysis

Al 0.005%  Mn 0.75%
Cr 0.04%  Si 0.03%
Cu 0.02%  Fe remainder

Interferences

The large excess of iron in the matrix causes interference effects in the determination of each of the trace elements. This is minimized by the use of standards which contain a similar amount of iron to that in the sample.

In the total trace element analysis of a complex sample, an alternative to employing individual element standards is to prepare a range of composite standards which have a base of the major matrix element. The same range of standards is then employed in all trace metal determinations in the parent sample. An example of this is given in the determination of Al, Cr, Cu, Mn, Si in iron alloy.

Aluminium is partially ionized in the nitrous oxide-acetylene flame. To suppress ionization, add potassium nitrate or chloride to give a final concentration of 1000 μg/mL potassium in all sample and standard solutions, including the blank.
Sample Preparation

Gently heat 2.000 g of sample with 25 mL 3:1 hydrochloric-nitric acid in a covered beaker. After the initial reaction has subsided, boil for 2–3 minutes to complete dissolution. Cool, transfer to a 100 mL volumetric flask and add 1 mL of a potassium chloride solution containing 100 g/L potassium. Make up to volume with distilled water.

For 0.005% Al, the sample solution will contain approximately 1 μg/mL Al with 1000 μg/mL potassium added.

Composite Standard Preparation

Prepare a range of composite standards containing a series of concentrations of Al, Cr, Cu, Mn, Si in a pure iron matrix. The solutions are prepared according to the schedules given in Tables 1 and 2.

NOTE To each composite standard solution, add potassium chloride to give a final concentration of 1000 μg/mL potassium.

Basic Matrix

Dissolve replicate 2.000 g lots of pure iron in 25 mL 3:1 hydrochloric-nitric acid.

Add aliquots of individual element solutions to give a range of standard concentrations in a final volume of 100 mL.

Element Addition Solutions

Refer to the individual element standard conditions for the preparation of standard stock solutions.

Prepare addition solutions at concentrations given in Table 1. Add aliquots of the addition solutions to the basic matrix above. Make up to 100 mL to give the range of standards in Table 2.

Table 1

For example:

Aluminium addition solution:

Refer to aluminium standard conditions.

Prepare a solution containing 10 μg/mL Al.

Prepare four composite standard solutions as specified in Table 2 using the basic matrix and the element addition solutions specified in Table 1. Thus for the aluminium addition, no aluminium stock solution (10 μg/mL) is added to ‘S1’, 5 mL is added to ‘S1’ and so on.

Now add element addition solutions for the other elements specified in Table 1 using appropriate aliquots of the element stock solutions. Add 1 mL of a solution containing 100 g/L potassium to each of the four composite standards. Finally, make up each of the four composite standards to 100 mL with distilled water.

The composite standards will contain 0, 0.5, 1, 1.5 μg/mL Al.
Cr (Chromium)

**Typical Analysis**
Refer to aluminium in iron alloy.

**Interferences**
A range of composite standards, prepared in a pure iron matrix, is used to compensate for the large excess of iron in the sample. Chemical interference by the iron is overcome by the use of a nitrous oxide-acetylene flame.

**Sample Preparation**
Refer to aluminium in iron alloy.

For 0.04% Cr, the sample solution concentration will be approximately 8 \( \mu g/mL \) Cr.

**Standard Preparation**
Refer to aluminium in iron alloy.

The composite standards will contain 0, 3, 7, 10 \( \mu g/mL \) Cr.

Cu (Copper)

**Typical Analysis**
Refer to aluminium in iron alloy.

**Interferences**
A range of composite standards, prepared in a pure iron matrix, is used to compensate for the large excess of iron in the sample.

**Sample Preparation**
Refer to aluminium in iron alloy.

For 0.02% Cu, the sample solution concentration will be approximately 4 \( \mu g/mL \) Cu.

**Standard Preparation**
Refer to aluminium in iron alloy.

The composite standards will contain 0, 2, 4, 6 \( \mu g/mL \) Cu.

K (Potassium)

**Typical Analysis**
Fe 63%  Ti 1.2%  Si 3%

K 0.09%  Al 1.4%  Na 0.17%

**Sample Preparation**
Take 0.5 g catchweight samples in PTFE beakers. Add 20 mL nitric acid and 10 mL hydrochloric acid and warm slowly. When the reaction subsides, heat to near boiling for 30 minutes, then cool. Add 10 mL hydrofluoric acid, keeping the temperature below 50 °C to avoid loss of silicon. Allow to stand for 5 minutes, then add 0.5 g boric acid to remove excess fluoride and dissolve any precipitated iron fluorides. Dilute to 100 mL, then further dilute 2 mL to 100 mL for potassium determination. For 0.09% K in a 0.5 g sample, the final solution concentration will be approximately 1 \( \mu g/mL \) K.

**Standard Preparation**
Refer to potassium standard conditions.

Prepare calibration standards of 0, 0.5, 1.0, 1.5 \( \mu g/mL \) K, each containing 600 \( \mu g/mL \) iron to approximate the sample solution matrix.

Mn (Manganese)

**Typical Analysis**
Refer to aluminium in iron alloy.

**Interferences**
A range of composite standards, prepared in a pure iron matrix, is used to compensate for the large excess of iron in the sample.

**Sample Preparation**
Refer to aluminium in iron alloy.

For 0.75% Mn, the sample solution concentration will be approximately 150 \( \mu g/mL \) Mn.

**Standard Preparation**
Refer to aluminium in iron alloy.

The composite standards will contain 0, 100, 150, 200 \( \mu g/mL \) Mn.

Si (Silicon)

**Typical Analysis**
Refer to aluminium in iron alloy.

**Interferences**
A range of composite standards, prepared in a pure iron matrix, is used to compensate for the large excess of iron in the sample.
Methodology

Sample Preparation
Refer to aluminium in iron alloy.
For 0.03% Si, the sample solution concentration will be approximately 6 µg/mL Si.

Standard Preparation
Refer to aluminium in iron alloy.
The composite standards will contain 0, 2.5, 5, 7.5 µg/mL Si.

Ferrosilicon

Al (Aluminium)

Range
0.2–5% Al

Typical Analysis
Ferrosilicon (FeSi) 90% Al 2% Ca 0.5%

Interferences
Silicon suppresses the aluminium absorbance by up to 30%. This is overcome by using standards containing silicon at the same concentration as the sample.
Aluminium is partially ionized in the nitrous oxide-acetylene flame. To suppress ionization, add potassium nitrate or chloride solution to give a final concentration or 2000 µg/mL potassium in all solutions including the blank.

Sample Preparation
Dissolve 1.000 g sample in 5 mL water, 10 mL nitric acid and 10 mL hydrofluoric acid in a PTFE beaker.
Evaporate to dryness and dissolve the residue in 10 mL nitric acid, 10 mL water and 5 mL of 10 volume hydrogen peroxide.
Dilute to 250 mL with the addition of potassium to a concentration of 2000 µg/mL. For 2% Al, the solution concentration will be approximately 80 µg/mL Al.

Standard Preparation
Refer to aluminium standard conditions.

Prepare calibration standards containing 0, 50, 100, 200 µg/mL Al. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above, the standards would contain:

\[
\begin{align*}
\text{Fe} & : 2400 \ \mu\text{g/mL} \\
\text{Si} & : 1200 \ \mu\text{g/mL} \\
\text{K} & : 2000 \ \mu\text{g/mL} \\
\text{HNO}_3 & : 4 \ \text{mL/100 mL}
\end{align*}
\]

Ca (Calcium)

Interferences
Silicon, aluminium and iron all depress the calcium absorbance to varying degrees. This is overcome by using a nitrous oxide-acetylene flame and by using standards containing these major matrix elements at the same concentration as the sample. Calcium is partially ionized in the nitrous oxide-acetylene flame. To suppress ionization add potassium nitrate or chloride to give final concentration of 2000 µg/mL potassium in all solutions including the blank.

Sample Preparation
Refer to aluminium in ferrosilicon.
For 0.5% Ca, the solution concentration will be approximately 20 µg/mL Ca.

Standard Preparation
Refer to calcium standard conditions.

Prepare calibration standards containing 0, 10, 20, 30 µg/mL Ca. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

\[
\begin{align*}
\text{Fe} & : 2400 \ \mu\text{g/mL} \\
\text{Si} & : 1200 \ \mu\text{g/mL} \\
\text{K} & : 2000 \ \mu\text{g/mL} \\
\text{HNO}_3 & : 4 \ \text{mL/100 mL}
\end{align*}
\]
Iron and Steel

Mg (Magnesium)

Range
0.001–0.25% Mg

Interferences
In the air-acetylene flame, aluminium depresses the Mg absorbance by 17–20% at the levels encountered in iron and steel.

This and other minor interferences can be overcome by the addition of 1500 μg/mL strontium to the sample solutions.

The method is satisfactory in the presence of the following elements:

- Ni 30%
- Cr 30%
- Cu 10%
- Mo 5%
- Mn 2%
- Si 2%
- Al 2%
- V 2%
- P 2%
- Zn 1%
- Ti 0.5%
- Pb 0.5%

Interferences are minimized without the need for a suppressor when the nitrous oxide-acetylene flame is used.

Reference

Sample Preparation
Dissolve 1.000 g of sample in 30 mL hydrochloric acid (1:1) and oxidize with 5 mL nitric acid. Evaporate to dryness and bake for 5 minutes at 200 °C. Extract the residue with 10 mL hydrochloric acid; heat for 5 minutes to ensure dissolution of the soluble salts. Dilute with 50 mL cold water and cool. Add 5 mL strontium solution (183 g/liter SrCl₂.2H₂O) and dilute to 200 mL in a graduated flask. Filter off a portion, discarding the first washings.

Standard Preparation
Refer to magnesium standard conditions.

Prepare calibration standards of a concentration range designed to cover the expected magnesium level in the sample solution.

The standard solutions must contain all reagents and major elements present in the sample solution at approximately the concentration of the sample.

Steels

Al (Aluminium)

Range
2–4% Al

Remainder: Cr, Ni, etc.

Interferences
Silicon suppresses the aluminium absorbance by up to 30%. This is overcome by using standards containing silicon at the same concentration as the sample.

Aluminium is partially ionized in the nitrous oxide-acetylene flame. To suppress ionization, add potassium nitrate or chloride solution to give a final concentration of 2000 μg/mL potassium in all solutions including the blank.

Sample Preparation
Dissolve 0.500 g sample in 20 mL nitric acid, 10 mL hydrochloric acid in a PTFE beaker. Heat to aid dissolution.

Cool; add 10 mL hydrofluoric acid slowly so that the temperature of the beaker is maintained at 50–60 °C to prevent volatilization of the silicon.

Add 0.5 g A.R. boric acid to complex excess hydrofluoric acid; add 0.2 g potassium as the nitrate and dilute to 100 mL.

For 3% Al, the solution concentration will be approximately 150 μg/mL Al.

Notes:
- If silicon, titanium and niobium are not present in the sample, the hydrofluoric acid treatment may be omitted.
- Use the method of standard additions to correct for the complex matrix of the sample solutions.

Standard Preparation
Refer to aluminium standard conditions.
Prepare standards containing 0, 50, 100 μg/mL added Al by pipetting aliquots of a 1000 μg/mL Al solution into 25 mL aliquots of the sample solution. Dilute to 50 mL.

**Mn (Manganese)**

**Typical Analysis**
Refer to aluminium in steels.

**Sample Preparation**
Refer to aluminium in steels. For 0.08% Mn the solution concentration will be 4 μg/mL Mn.

**Standard Preparation**
Refer to manganese standard conditions. Only the 1000 μg/mL Mn standard solution is required. The standard addition procedure is used to avoid matching the complicated solution matrix.

**Na (Sodium)**

**Typical Analysis**
Refer to aluminium in steels.

**Sample Preparation**
Refer to aluminium in steels. For 0.17% Na in a 0.500 g sample the solution concentration will be 8.5 μg/mL.

**Standard Preparation**
Refer to sodium standard conditions. Dilute the 1000 μg/mL standard solution to 100 μg/mL. The standard addition method is used so that matrix matching is unnecessary.

**Si (Silicon)**

**Typical Analysis**
Refer to aluminium in steels.

**Sample Preparation**
Refer to aluminium in steels.

**Standard Preparation**
Refer to silicon standard conditions. Prepare standards containing 0, 20, 40 μg/mL added Si by pipetting 0, 1, 2 mL aliquots of a 1000 μg/mL Si standard into 25 mL aliquots of sample solution. Dilute to 50 mL.

**Ti (Titanium)**

**Typical Analysis**
Refer to aluminium in steels.

**Sample Preparation**
Refer to aluminium in steels. For 1.2% Ti, the solution concentration will be approximately 60 μg/mL Ti.

**Standard Preparation**
Refer titanium standard conditions. Only the 1000 μg/mL stock solution is required; the standard addition method is used to avoid matching samples and standards.

**V (Vanadium)**

**Typical Analysis**
Refer to aluminium in steels.

**Interferences**
Many elements present will interfere. Use the method of standard additions to compensate for the interferences.

**Sample Preparation**
Refer to aluminium in steels.

**Standard Preparation**
Refer to vanadium standard conditions. An aqueous solution only is required as the method of standard additions is used.

**Stainless Steel**

**Cr (Chromium)**

**Typical Analysis**
Cr  15%  Nb  1%  Si  0.5%  Mn  2%  Ni  8%  Ta  0.04%  Mo  0.03%  Fe  remainder

**Interferences**
A nitrous oxide-acetylene flame is used to overcome chemical interference from iron and nickel. 50% (v/v) ethanol is added to improve sensitivity.
Sample Preparation
Refer to niobium in stainless steel.
Take 2 mL of the prepared solution, add 2 mL hydrochloric acid and 50 mL ethanol. Dilute to 100 mL with distilled water.
For 15% Cr, the dilute solution will contain approximately 75 μg/mL Cr.

Standard Preparation
Refer to chromium standard conditions.
Prepare calibration standards containing 0, 25, 50, 75, 100 μg/mL Cr. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration.
For example, in the typical case above the standards would contain:

Fe 500 μg/mL
Cr 75 μg/mL
Ni 40 μg/mL
hydrochloric acid 2 mL/100 mL
ethanol 50 mL/100 mL

Mn (Manganese)

Typical Analysis
Refer to chromium in stainless steel.

Interferences
50% (v/v) ethanol is added to improve sensitivity and minimize interferences.

References

Sample Preparation
Refer to niobium in stainless steel.
Take 2 mL of the prepared solution, add 2 mL hydrochloric acid and 50 mL ethanol. Dilute to 100 mL with distilled water.
For 2% Mn, the dilute solution will contain approximately 10 μg/mL Mn.

Standard Preparation
Refer to manganese standard conditions.
Prepare calibration standards containing 0, 5, 10, 15, 20 μg/mL Mn. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration.
For example, in the typical case above the standards would contain:

Fe 500 μg/mL
Cr 75 μg/mL
Ni 40 μg/mL
hydrochloric acid 2 mL/100 mL
ethanol 50 mL/100 mL

Mo (Molybdenum)

Range
0.2%–0.8% Mo

Sample Preparation
Dissolve 1.000 g samples in 30 mL dilute aqua regia (1:1). Boil for 5 minutes, add 30 mL water, filter and dilute to 250 mL. For 0.5% Mo in a 1.000 g sample, the solution concentration is 20 μg/mL Mo.

Standard Preparation
Refer to molybdenum standard conditions.
Prepare calibration standards containing 0, 15, 20, 30 μg/mL Mo, each containing 3000 μg/mL Fe to approximately match the samples.
For 8% Ni, the dilute solution will contain approximately 40 μg/mL Ni.

**Standard Preparation**

Refer to nickel standard solutions.

Prepare calibration standards containing 0, 10, 30, 50 μg/mL Ni. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration.

For example, in the typical case above the standards would contain:

- Fe 500 μg/mL
- Cr 75 μg/mL
- hydrochloric acid 2 mL/100 mL
- ethanol 50 mL/100 mL

**Nb (Niobium)**

**Typical Analysis**

Refer to chromium in stainless steel.

**Interferences**

Many of the elements present interfere. Add ammonium fluoride and ethanol to the solution to increase the niobium absorbance and suppress the interferences.

**References**

**Sample Preparation**

Dissolve 2.5 g samples in 10 mL hydrochloric acid, with careful dropwise addition of 3 mL nitric acid and 2 mL hydrofluoric acid in a PTFE beaker. Evaporate to moist salts. Dissolve the salts in 5 mL hydrochloric acid, 2 mL hydrofluoric acid and 5 mL water. Add 10 mL 1 M ammonium fluoride and 50 mL ethanol, and dilute to 100 mL in a plastic volumetric flask. For 1% Nb the solution concentration will be 250 μg/mL.

**Standard Preparation**

Refer to niobium standard conditions.

Prepare calibration standards containing 0, 100, 150, 200, 250 μg/mL Nb. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- HCl 5%
- HF 2%
- Ethanol 50%
- NH₄F 10 mL/100 mL of 1 M solution
- Fe 2.5 g/100 mL

**Ta (Tantalum)**

**Typical Analysis**

Refer to chromium in stainless steel.

**Interferences**

Ammonium fluoride and ethanol are used to improve the sensitivity and minimize interferences.

**Sample Preparation**

Refer to niobium in stainless steel.

For 0.04% Ta, the solution concentration will be approximately 10 μg/mL Ta.

**Standard Preparation**

Refer tantalum standard conditions.

Prepare calibration standards containing 0, 5, 10, 15, 20 μg/mL Ta. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:
Methodology

HCl  5 mL/100 mL
Cr  3750 μg/mL
HF  2 mL/100 mL
Ni  2000 μg/mL
NH₄F  10 mL/100 mL
Mn  500 μg/mL
of 1 M solution
Fe  2.5 g/100 mL
Nb  250 μg/mL
Ethanol  50 mL/100 mL

Aluminium Alloy

Zn (Zinc)

Typical Analysis (High-Silicon Alloy)

Cu  2%  Mg  0.1%  Si  5%
Fe  1%  Mn  0.5%  Ni  0.3%
Zn  0.4%  Ti  0.2%  Al remainder

Interferences
In the high-matrix solution used in this method, non-atomic absorption will be important. Use a background corrector.

Sample Preparation
React 0.500 g samples with 4 g sodium hydroxide and 10 mL water in zirconium crucibles. When the reaction has ceased, dry the reaction mixture and fuse at a dull red heat until a clear melt is obtained.

Dissolve the cooled cake in 75 mL water, 15 mL hydrochloric acid and 2 mL nitric acid. Add 5 mL 10 volume hydrogen peroxide if necessary to clear the solution. Dilute to 500 mL. For 0.4% Zn in a 0.500 g sample, this solution contains 4 μg/mL Zn.

Standard Preparation
Refer zinc standard conditions.

Prepare calibration standards containing 0, 2.5, 5, 7.5 μg/mL Zn. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

Al  1000 μg/mL
NaOH  4 g/500 mL
HCl  15 mL/500 mL

Aluminium-Silicon Alloy

Al (Aluminium)

Typical Analysis

Al  84.7%  Mg  0.02%  Si  13.2%
Cu  1.0%  Mn  0.13%  Sn  0.05%
Fe  0.4%  Pb  0.05%  Zn  0.45%

Interferences
Aluminium is partially ionized in the nitrous oxide-acetylene flame. To suppress ionization, add potassium nitrate or chloride to give a final concentration of 2000 μg/mL potassium in all solutions including the blank.

Sample Preparation
Place 1.000 g of sample into a covered PTFE beaker in a cooling bath. Add 20 mL hydrochloric acid dropwise, allowing the reaction to subside between additions.

WARNING
The reaction is vigorous and the beaker should be cooled during the addition of the acid or else a serious injury could result.

Add 4 mL hydrofluoric acid and allow to stand for 10 minutes, taking care that the temperature does not exceed 50–60 °C. Add 4 mL nitric acid dropwise; again taking care to cool the mixture during reaction. Cool and add 0.5 g A.R. boric acid to complex the excess fluorides. Transfer to a 100 mL volumetric flask and make up to volume with distilled water.

For analysis, take 5 mL of the prepared solution, add 2 mL of a solution containing 100 g/L potassium and make up to 100 mL with distilled water.

For 84.7% Al, the analytical solution will contain approximately 425 μg/mL Al with 2000 μg/mL potassium added.
Methodology

**Standard Preparation**
Refer to aluminium standard conditions.
Prepare calibration standards containing 0, 200, 300, 400, 500 μg/mL Al. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Si 70 μg/mL
- K 2000 μg/mL
- hydrochloric acid 1 mL/100 mL
- boric acid 0.025 g/100 mL

**Cu (Copper)**

**Typical Analysis**
Refer to aluminium in aluminium-silicon alloy.

**Sample Preparation**
Refer to aluminium in aluminium-silicon alloy.
Use the diluted solution; for 1.0% Cu, the solution concentration will be approximately 5 μg/mL Cu.

**Standard Preparation**
Refer to copper standard conditions.
Prepare calibration standards containing 0, 2, 4, 6 μg/mL Cu. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Al 425 μg/mL
- Si 70 μg/mL
- K 2000 μg/mL
- hydrochloric acid 1 mL/100 mL
- boric acid 0.025 g/100 mL

**Fe (Iron)**

**Typical Analysis**
Refer to aluminium in aluminium-silicon alloy.

**Sample Preparation**
Refer to aluminium in aluminium-silicon alloy.
Use the diluted solution; for 0.02% Mg the solution concentration will be approximately 0.1 μg/mL Mg.

**Standard Preparation**
Refer to magnesium standard conditions.

**Interferences**
A nitrous oxide-acetylene flame is used to overcome possible chemical interference from the complex matrix.

**Sample Preparation**
Refer to aluminium in aluminium-silicon alloy.
Use the undiluted solution; for 0.4% Fe, the solution concentration will be approximately 40 μg/mL Fe.

**Standard Preparation**
Refer to iron standard conditions.
Prepare calibration standards containing 0, 20, 30, 40, 50 μg/mL Fe. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Al 8500 μg/mL
- Si 1300 μg/mL
- hydrochloric acid 20 mL/100 mL
- nitric acid 4 mL/100 mL
- hydrofluoric acid 4 mL/100 mL
- boric acid 0.5 g/100 mL

**Mg (Magnesium)**

**Typical Analysis**
Refer to aluminium in aluminium-silicon alloy.

**Interferences**
A nitrous oxide-acetylene flame is used to overcome interference from the aluminium-silicon matrix.

**Sample Preparation**
Refer to aluminium in aluminium-silicon alloy.
Use the dilute solution; for 0.02% Mg the solution concentration will be approximately 0.1 μg/mL Mg.

**Standard Preparation**
Refer to magnesium standard conditions.
Prepare calibration standards containing 0, 0.05, 0.1, 0.2 μg/mL Mg. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Al: 425 μg/mL
- Si: 70 μg/mL
- K: 2000 μg/mL
- Hydrochloric acid: 1 mL/100 mL
- Boric acid: 0.025 g/100 mL

**Mn (Manganese)**

**Typical Analysis**
Refer to aluminium in aluminium-silicon alloy.

**Sample Preparation**
Refer to aluminium in aluminium-silicon alloy.

Use the undiluted solution; for 0.13% Mn, the solution concentration will be approximately 13 μg/mL Mn.

**Standard Preparation**
Refer to manganese standard conditions.

Prepare calibration standards containing 0, 10, 15, 20 μg/mL Mn. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Al: 8500 μg/mL
- Si: 1300 μg/mL
- Hydrochloric acid: 20 mL/100 mL
- Nitric acid: 4 mL/100 mL
- Hydrofluoric acid: 4 mL/100 mL
- Boric acid: 0.5 g/100 mL

**Si (Silicon)**

**Typical Analysis**
Refer to aluminium in aluminium-silicon alloy.

**Sample Preparation**
Refer to aluminium in aluminium-silicon alloy.

Use the dilute solution; for 13.2% Si, the solution concentration will be approximately 70 μg/mL Si.

**Standard Preparation**
Refer to silicon standard conditions.

Prepare calibration standards containing 0, 50, 75, 100 μg/mL Si. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Al: 8500 μg/mL
- Si: 1300 μg/mL
- Hydrochloric acid: 20 mL/100 mL
- Nitric acid: 4 mL/100 mL
- Hydrofluoric acid: 4 mL/100 mL
- Boric acid: 0.5 g/100 mL

**Pb (Lead)**

**Typical Analysis**
Refer to aluminium in aluminium-silicon alloy.

**Sample Preparation**
Refer to aluminium in aluminium-silicon alloy.

Use the undiluted solution; for 0.05% Pb, the solution concentration will be approximately 5 μg/mL Pb.

**Standard Preparation**
Refer to lead standard conditions.

Prepare calibration standards containing 0, 2, 4, 6, 8 μg/mL Pb. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Al: 8500 μg/mL
- Si: 1300 μg/mL
- Hydrochloric acid: 20 mL/100 mL
- Nitric acid: 4 mL/100 mL
- Hydrofluoric acid: 4 mL/100 mL
- Boric acid: 0.5 g/100 mL

**Interferences**
At the 217.0 nm wavelength, non-atomic species in the air-acetylene flame absorb strongly. Use a background corrector to check for the presence of non-atomic absorption.

**Sample Preparation**
Refer to aluminium in aluminium-silicon alloy. Use the undiluted solution; for 0.05% Pb, the solution concentration will be approximately 5 μg/mL Pb.
**Methodology**

Al 425 µg/mL
K 2000 µg/mL
hydrochloric acid 1 mL/100 mL
boric acid 0.025 g/100 mL

**Sn (Tin)**

**Typical Analysis**
Refer to aluminium in aluminium-silicon alloy.

**Interferences**
At 224.6 nm, non-atomic species in the flame may absorb strongly. Use a background corrector to check for the presence of non-atomic absorption.

**Sample Preparation**
Refer to aluminium in aluminium-silicon alloy.
Use the undiluted solution; for 0.05% Sn, the solution concentration will be approximately 5 µg/mL Sn.

**Standard Preparation**
Refer to tin standard conditions.
Prepare calibration standards containing 0, 2, 4, 6, 8 µg/mL Sn. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

<table>
<thead>
<tr>

**Zn (Zinc)**

**Typical Analysis**
Refer to aluminium in aluminium-silicon alloy.

**Interferences**
At the 213.9 nm wavelength, non-atomic species in the flame absorb strongly. Use a background corrector to check for the presence of non-atomic absorption.

**Sample Preparation**
Refer to aluminium in aluminium-silicon alloy.
Use the dilute solution; for 0.45% Zn, the solution concentration will be approximately 2 µg/mL Zn.

**Standard Preparation**
Refer to zinc standard conditions.
Prepare calibration standards containing 0, 0.5, 1.0, 2.0, 2.5 µg/mL Zn. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

<table>

**Copper-Beryllium Alloy**

**Be (Beryllium)**

**Typical Analysis**
Be 2%  Cu 98%

**Sample Preparation**
Dissolve 1.000 g of alloy in 5 mL dilute nitric acid (1:4) without heating. Dilute to 1 liter with distilled water. For 2% Be, the solution concentration will be approximately 20 µg/mL Be.
**Standard Preparation**

Refer to beryllium standard conditions. Prepare calibration standards containing 0, 10, 20, 30 μg/mL Be. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Cu 2000 μg/mL

**Brass**

**Cu (Copper)**

**Typical Analysis**

- Cu 70%  Zn 29%  Fe 0.01%

**Sample Preparation**

Dissolve 1.000 g of brass in 5 mL of hydrochloric acid and 5 mL of nitric acid. When the initial reaction has ceased, heat to near boiling for 5–10 minutes.

Cool and dilute to 500 mL.

For 70% Cu, the solution concentration will be approximately 1400 μg/mL Cu.

**Standard Preparation**

Refer to copper standard conditions.

Prepare calibration standards containing 0, 1000, 1500, 2000 μg/mL Cu. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Zn 600 μg/mL

**Ni (Nickel)**

**Typical Analysis**

- Cu 82%  Zn 5%  Sn 5%
- Ni 1%  Pb 4%  Sb 0.1%

**Sample Preparation**

Dissolve 1.000 g samples in 10 mL 1:1 hydrochloric acid and 2 mL nitric acid, and dilute to 100 mL. For 0.05% Sn the solution concentration will be approximately 5 μg/mL Sn.

**Standard Preparation**

Refer to nickel standard conditions.

Prepare standards containing 0, 30, 40, 50 μg/mL Ni, each containing 3500 μg/mL Cu and acids to match the sample solution.

**Sn (Tin)**

**Typical Analysis**

- Cu 60%  Zn 38%  Sn 0.05%
- Pb 1.5%  Al 0.2%

**Interferences**

At 224.6 nm, non-atomic species may absorb strongly in the air-hydrogen flame. Use a background corrector to check for the presence of non-atomic absorption.

**Sample Preparation**

Dissolve 1.000 g samples in 10 mL 1:1 hydrochloric acid and 2 mL nitric acid, and dilute to 100 mL. For 0.05% Sn the solution concentration will be approximately 5 μg/mL Sn.

**Standard Preparation**

Refer to tin standard conditions.

Prepare standards containing 0, 2, 4, 6 μg/mL Sn.

Each standard solution must contain the same reagents and major matrix elements as the sample at approximately the same concentrations. For the typical sample above the standards should contain:

- Cu 6000 μg/mL
- Zn 4000 μg/mL
- HCl 5%
- HNO₃ 2%

**Bronze**

**Al (Aluminium)**

**Range**

0–20% Al
Methodology

Typical Analysis

Cu 82%  Fe 3%  Pb 4%
Ni 1.3%  Zn 0.01%  Al 9%
Sb 0.1%

Interferences

Aluminium is partially ionized in the nitrous oxide-acetylene flame. To suppress ionization, add potassium nitrate or chloride to give final concentration of 2000 μg/mL potassium in all solutions including the blank.

Sample Preparation

Dissolve 1.000 g bronze in 20 mL hydrochloric acid, 10 mL nitric acid and 5 mL water. Evaporate down to approximately 5 mL and then dilute to 1000 mL with the addition of 2.0 g potassium as the nitrate.

For 9% Al, the solution concentration will be approximately 90 μg/mL Al.

Standard Preparation

Refer to aluminium standard conditions.

Prepare calibration standards containing 0, 50, 100, 150 μg/mL Al.

The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

Cu 800 μg/mL
Fe 30 μg/mL
Pb 40 μg/mL
Ni 15 μg/mL
K 2000 μg/mL

Fe (Iron)

Typical Analysis

Refer to aluminium in bronze.

Sample Preparation

Refer to aluminium in bronze.

For 3% Fe, the solution concentration will be approximately 30 μg/mL Fe.

Standard Preparation

Refer to iron standard conditions.

Prepare calibration standards containing 0, 20, 30, 40 μg/mL Fe. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

Cu 8200 μg/mL
Al 90 μg/mL
Pb 40 μg/mL
Sb 10 μg/mL
Ni 10 μg/mL

Pb (Lead)

Typical Analysis

Refer to aluminium in bronze.

Interferences

No interferences have been reported.

Sample Preparation

Refer to aluminium in bronze.

For 4% Pb, the solution concentration will be approximately 40 μg/mL Pb.

Standard Preparation

Refer to lead standard conditions.

Prepare calibration standards containing 0, 30, 40, 50 μg/mL Pb. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

Al 100 μg/mL
Cu 800 μg/mL
Fe 30 μg/mL
Ni 15 μg/mL

Sb (Antimony)

Range

Up to 0.5% in bronze and brass.

Typical Analysis

Refer to aluminium in bronze.
Interferences
At 217.6 nm, non-atomic species in the air-acetylene flame may absorb strongly. Use a background corrector to check for the presence of non-atomic absorption.

Sample Preparation
Dissolve 1.000 g samples in 5 mL hydrochloric acid and 5 mL nitric acid, with gentle warming. Do not boil the solution. When the reaction is complete, dilute quantitatively to 100 mL. For 0.1% Sb in a 1.000 g sample, the solution concentration is 10 μg/mL Sb.

Standard Preparation
Refer antimony standard conditions.

Prepare calibration standards containing 0, 10, 20, 30, 40, 50 μg/mL Sb. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

<table>
<thead>
<tr>
<th>Element</th>
<th>Concentration</th>

</tr>
</tbody>
</table>

Cadmium Alloys

Cd (Cadmium)

Typical Analysis
Cd 20%  Ag 50%  Cu 15%
Zn 15%

Sample Preparation
Dissolve 0.500 g of alloy in 25 mL of 1:1 nitric acid and dilute to 200 mL.

For 20% Cd, the solution concentration will be approximately 500 μg/mL Cd.

Standard Preparation
Refer to cadmium standard conditions.

Prepare calibration standards containing 0, 250, 500, 750 μg/mL Cd. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

<table>
<thead>
<tr>
<th>Element</th>
<th>Concentration</th>

Cobalt and Nickel Alloys

Co (Cobalt)

Typical Analysis
Cobalt alloy  Co 63%  Cr 27%  W 5%  Fe 5%
Nickel alloy  Co 1%  Cr 13%  Ni 65%  Fe 5%

Interferences
The high chromium and nickel levels can lead to interference in the presence of hydrochloric acid. The use of a nitrous oxide-acetylene flame will remove the interference.

Sample Preparation
Digest 0.500 g sample in a PTFE beaker with 2 mL water, 10 mL hydrochloric acid and 5 mL nitric acid.

Add 2 mL nitric acid and 5 mL hydrochloric acid and reheat for another 30 minutes.

Cool, add 5 mL hydrofluoric acid and fume to dryness. Add 5 mL nitric acid and heat for 10 minutes. Repeat with a further 5 mL nitric acid.

Add 10 mL hydrochloric acid and reheat to boiling, cool, dilute to 100 mL.

For 1% Co, the solution concentration will be approximately 50 μg/mL Co.

Standard Preparation
Refer to cobalt standard conditions.

Prepare calibration standards containing 0, 50, 100, 150 μg/mL Co.

The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

<table>
<thead>
<tr>
<th>Element</th>
<th>Concentration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ni</td>
<td>3250 μg/mL</td>
</tr>
<tr>
<td>Cr</td>
<td>650 μg/mL</td>
</tr>
<tr>
<td>Fe</td>

<tr>
<td>HCl</td>
<td>10 mL/100 mL</td>
</tr>
</tbody>
</table>
Jewelry Clippings

Au (Gold)

Range
0.05 μg/g–50%

Interferences
Inter-element interferences are minimized by application of the standard addition method.

Sample Preparation
Dissolve 0.5000 g of jewellery clippings in aqua regia (mixture of nitric acid and hydrochloric acid in a ratio of 1:3). Make up to 100 mL with distilled water. Take 10 mL of this solution and dissolve with distilled water to 100 mL. For a sample containing 5% gold, the dilute solution will contain 25 μg/mL Au.

Standard Preparation
Pipette 5 mL aliquots of the sample solution into five 10 mL volumetric flasks. Add 0, 1, 2, 3, 5 mL of 20 μg/mL Au solution and make up to volume with distilled water.

The prepared standards will contain 0, 2, 4, 6, 10 μg/mL added gold.

Pd (Palladium)

Range
0.05 μg/mL–5%

Interferences
A method of standard additions is used to overcome matrix interferences.

In the presence of high levels of aluminium, cobalt or nickel, signal depression can be eliminated by addition of lanthanum (5000 μg/mL as chloride) or EDTA (0.01 M) to all solutions.

Sample Preparation
Prepare as for gold in jewellery clippings procedure. Include dilution of 10 mL sample solution to 100 mL as indicated.

For a sample containing 2% Pd, the dilute solution will contain 10 μg/mL added palladium.

Standard Preparation
Prepare 20 μg/mL Pd solution by dilution of 2 mL of 1000 μg/mL Pd solution to 100 mL.

Pt (Platinum)

Range
0.05 μg/mL–20%

Interferences
Signal depression caused by presence of other noble metals in solution can be eliminated by addition of lanthanum (1%) or copper (2%) to all solutions. The standard addition method recommended here will minimize the effect of inter-element interferences.

Sample Preparation
Dissolve 0.5000 g of jewellery clippings in aqua regia. Make up to 100 mL with distilled water. For a sample containing 2% platinum, the solution will contain 100 μg/mL Pt.

Standard Preparation
Dilute 20 mL of 1000 μg/g Pt solution to 100 mL to obtain 200 μg/mL Pt standard.

Standard Addition
Pipette 5 mL aliquots of the sample solution into five 10 mL volumetric flasks. Add 0, 1, 2, 5 mL of 200 μg/mL Pt solution and make up to volume with distilled water.

The prepared standards will contain 0, 20, 40, 100 μg/mL added platinum.

Lead Alloy

As (Arsenic)

Range
0.01–0.1% As

Typical Analysis
Pb 76%  Sb 13%  Sn 10%  Zn 0.004%  Ni 0.003%  As 0.04%
Sample Preparation
Dissolve 0.500 g of alloy in 2 mL hydrofluoric acid, 5 mL nitric acid and 10 mL water in a PTFE beaker.
Dilute to 100 mL in a plastic volumetric flask.
For 0.04% As, the solution concentration will be approximately 2.0 μg/mL As.

Standard Preparation
Refer to arsenic standard conditions.
Prepare calibration standards containing 0, 1, 2, 5 μg/mL As.
The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration.
For example, in the typical case above the standards would contain:

- Pb 3800 μg/mL
- Sb 650 μg/mL
- Sn 500 μg/mL
- HF 2 mL/100 mL
- HNO₃ 5 mL/100 mL

Nickel Alloy

Ag (Silver)

Typical Analysis
Ag 10 μg/g

Sample Preparation
Accurately weigh 2.000 g of sample into a 150 mL PTFE beaker and add a mixture of 12 mL hydrochloric acid, 6 mL nitric acid and 20 mL water. Heat on a sand bath for 15 minutes, boil to reduce the volume to 10 mL and cool.
Add 1 mL hydrofluoric acid dropwise before boiling for a further 5 minutes. Cool and dilute to 50 mL in a plastic volumetric flask.
For 10 μg/g Ag, the solution concentration will be 4 μg/mL Ag.

Standard Preparation
Refer silver standard conditions.

Prepare calibration standards containing 0, 0.2, 0.4, 0.6 μg/mL Ag. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Cr 2000 μg/mL
- Ni 10000 μg/mL
- Al 900 μg/mL
- Ti 500 μg/mL
- HF 2 mL/100 mL
- HCl 8 mL/100 mL
- HNO₃ 6 mL/100 mL

Bi (Bismuth)

Typical Analysis
Bi 0.003%

Interferences
Non-atomic absorption due to the high solids concentration will necessitate the use of background correction.
The high nickel/bismuth ratio will result in some chemical interference. This is overcome by adding the major matrix elements to the standards at the same concentration as that of the sample solution.

Sample Preparation
Dissolve 2.000 g sample in 12 mL hydrochloric acid, 6 mL nitric acid and 20 mL water in a PTFE beaker. Evaporate the solution to 10–12 mL, cool, add 1 mL hydrofluoric acid dropwise and boil for 5 minutes.
Cool, add 5 mL 1% boric acid solution and dilute to 50 mL.
For 0.003% Bi the solution concentration will be approximately 1 μg/mL Bi.

Standard Preparation
Refer to bismuth standard conditions.
Prepare calibration standards containing 0, 1, 1.5, 2.0 μg/mL Bi. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

<table>
<thead>
<tr>
<th>Element</th>
<th>Concentration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ni</td>
<td>22000 μg/mL</td>
</tr>
<tr>
<td>Cr</td>
<td>4000 μg/mL</td>
</tr>
<tr>
<td>Al</td>
<td>2000 μg/mL</td>
</tr>
<tr>
<td>Ti</td>
<td>2000 μg/mL</td>
</tr>
</tbody>
</table>

Cr (Chromium)

Typical Analysis
Cr 15%

Interferences
As noted in standard conditions, interference from nickel will be observed. It is advisable to adjust the fuel flow until the absorbance obtained from a pure 1500 μg/mL Cr solution and a sample of 1500 μg/mL Cr plus nickel at the sample level produce the same absorbance. This procedure will be found to completely eliminate nickel interference.

Sample Preparation
Dissolve 1.000 g of fine turnings in 10 mL hydrochloric acid and 10 mL nitric acid. Heat gently until the cessation of nitrogen dioxide fumes. Transfer to a PTFE beaker and add 5 mL hydrofluoric acid in a dropwise manner. Ensure that the solution temperature does not exceed 30°C.

Transfer the solution to a 100 mL plastic volumetric flask and make up to volume with water.

For 15% Cr, the solution concentration will be approximately 1500 μg/mL Cr.

Standard Preparation
Refer to chromium in nickel alloys.

Prepare calibration standards containing 0, 50, 100, 150 μg/mL Fe. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

<table>
<thead>
<tr>
<th>Element</th>
<th>Concentration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cr</td>
<td>150 μg/mL</td>
</tr>
<tr>
<td>Ni</td>
<td>700 μg/mL</td>
</tr>
<tr>
<td>Co</td>
<td>10 μg/mL</td>
</tr>
<tr>
<td>HF</td>
<td>0.5 mL/100 mL</td>
</tr>
<tr>
<td>HCl</td>
<td>0.5 mL/100 mL</td>
</tr>
</tbody>
</table>

Fe (Iron)

Typical Analysis
Fe 14%

Interference
The high nickel/iron ratio can cause interference in an air-acetylene flame. The use of a nitrous oxide-acetylene flame is recommended to overcome this effect.

Sample Preparation
Refer to chromium in nickel alloys.

Dilute 10 mL of sample solution to 100 mL.

For 14% Fe, the final solution concentration will be 140 μg/mL Fe.

Standard Preparation
Refer to iron standard conditions.

Prepare calibration standards containing 0, 50, 100, 150 μg/mL Fe. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

<table>
<thead>
<tr>
<th>Element</th>
<th>Concentration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cr</td>
<td>150 μg/mL</td>
</tr>
<tr>
<td>Ni</td>
<td>700 μg/mL</td>
</tr>
<tr>
<td>Co</td>
<td>10 μg/mL</td>
</tr>
<tr>
<td>HF</td>
<td>0.5 mL/100 mL</td>
</tr>
<tr>
<td>HCl</td>
<td>0.5 mL/100 mL</td>
</tr>
</tbody>
</table>

Pb (Lead)

Typical Analysis
Pb 0.0025%
Methodology

Interferences
At 217 nm, non-atomic species in the air-acetylene flame may absorb strongly. Use a background corrector to check for the presence of non-atomic absorption. The 283.3 nm lead line normally has lower background absorption.

Sample Preparation
Refer to bismuth in nickel alloys.

For 0.0025% Pb, the solution concentration will be approximately 1 μg/mL Pb.

Standard Preparation
Refer to lead standard conditions.

Prepare calibration standards containing 0, 1, 2, 3 μg/mL Pb.

The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

Ni 22000 μg/mL  HCl 8 mL/100 mL
Cr 4000 μg/mL  HNO₃ 4 mL/100 mL
Al 2000 μg/mL  HF 2 mL/100 mL
Ti 2000 μg/mL  Boric acid solution 0.1%

Si (Silicon)

Typical Analysis
Si 0.5%

Sample Preparation
Refer to chromium in nickel alloy.

For 0.5% Si, the solution concentration will be approximately 50 μg/mL Si.

Standard Preparation
Refer to silicon standard conditions.

Prepare calibration standards containing 0, 25, 50, 75 μg/mL Si. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

Ni 7000 μg/mL  Co 100 μg/mL
Cr 1500 μg/mL  Si 50 μg/mL
Fe 1400 μg/mL
HF 5 mL/100 mL
HCl 10 mL/100 mL

Niobium Alloy

Nb (Niobium)

Typical Analysis
Nb 52%

Sample Preparation
Dissolve 0.200 g samples in 10 mL hydrofluoric acid and 3 mL nitric acid in a PTFE beaker. Evaporate to dryness, cool and dissolve the solids in 4 mL hydrofluoric acid and 3 mL nitric acid. Dilute to 100 mL in a plastic volumetric flask. For 52% Nb in a 0.200 g sample, the solution concentration will be approximately 1000 μg/mL Nb.

Standard Preparation
Refer to niobium standard conditions.

Prepare calibration standards containing 0, 500, 1000, 1500 μg/mL Nb. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

HF 4%
HNO₃ 3%
Ti 1000 μg/mL

Ti (Titanium)

Typical Analysis
Ti 48%

Sample Preparation
Refer to niobium in niobium alloy.

For 48% Ti, the solution concentration will be approximately 950 μg/mL Ti.

Standard Preparation
Refer to niobium standard conditions.
Prepare calibration standards containing 0, 500, 1000, 1500 μg/mL Ti. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- HF: 4%
- HNO₃: 4%
- Nb: 1000 μg/mL

**Silver Alloys**

**Ag (Silver)**

**Typical Analysis**

Ag 51%  Cu 15%  Zn 15%

Cd 19%

**Sample Preparation**

Dissolve 1.000 g of alloy in 25 mL of 1:1 nitric acid and dilute to 100 mL.

Further dilute 25 mL to 1 liter.

For 51% Ag, the solution concentration will be approximately 130 μg/mL Ag.

**Standard Preparation**

Refer silver standard conditions.

Prepare calibration standards containing 0, 100, 120, 130, 150 μg/mL Ag. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Cu: 37 μg/mL
- Zn: 37 μg/mL
- Cd: 47 μg/mL
- HNO₃: 0.3 mL/100 mL

**Soldering Stannum**

**Pb (Lead)**

**Typical Analysis**

Sn 60%  Pb 40%  Bi 0.005%

Al 0.01%  Sb 0.0015%

**Sample Preparation**

Refer antimony standard conditions.

Dilute 2 mL of sample solution to 200 mL.

For 40% Pb, the solution concentration will be approximately 20 μg/mL Pb.

**Standard Preparation**

Refer to lead standard conditions.

Prepare calibration standards containing 0, 10, 20, 30 μg/mL Pb. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

10% tartaric acid 0.25 mL/100 mL

**Sb (Antimony)**

**Range**

0–20 μg/g Sb

**Typical Analysis**

Refer to lead in soldering stannum.

**Interferences**

No chemical interferences are expected, although at 217.6 nm non-atomic species in the air-acetylene flame may absorb strongly. Use a background corrector to check for the presence of non-atomic absorption.

**Sample Preparation**

Dissolve 1.000 g samples in a mixture of 10 mL hydrochloric acid, 5 mL nitric acid and 50 mL 10% tartaric acid, with gentle warming. Do not boil the solution. When the reaction is complete, dilute quantitatively to 200 mL. For 15 μg/g Sb in 1.000 g samples, the solution concentration will be 7.5 μg/mL Sb.

**Standard Preparation**

Refer antimony standard conditions.

Prepare calibration standards containing 0, 2, 4, 6, 8, 10 μg/mL Sb. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:
Tin Lead Solder

Cu (Copper)

Ranges in a typical sample
- Sn: 30–60%
- Pb: 30–60%
- Cu: 50–200 μg/g
- Al: 20–100 μg/g

Sample Preparation
Place 0.5000 g sample in a beaker with 20 mL aqua regia (hydrochloric acid/nitric acid mixture in a ratio 3:1). Warm gently; do not allow to boil. Dilute the solution to 100 mL with distilled water.

For a sample containing 120 μg/g Cu, the solution will contain 0.6 μg/mL Cu.

Standard Preparation
Prepare standards containing 0, 100, 200, 400, 500 μg/mL Cu. Each standard solution must contain the same reagents and major matrix elements as the sample at similar levels. For a typical sample, each standard will contain:
- Pb: 300–5600 μg/mL
- HCl: 6 mL/100 mL
- HNO₃: 2 mL/100 mL
- Tartaric acid: 1.0%

Zinc Alloy

Al (Aluminium)

Range
2–8% Al

Typical Analysis
- Al: 4.7%
- Fe: 0.015%
- Cd: 0.0005%
- Mg: 0.045%
- Cu: 0.95%
- Pb: 0.003%
- Zn: remainder

Interferences
The large concentration of zinc in the sample matrix causes interferences to the determination of all of the trace elements. A range of composite standards, based upon a pure zinc matrix, is used to compensate for this interference.

Aluminium is partially ionized in the nitrous oxide-acetylene flame. To suppress ionization, add potassium nitrate or chloride solution to give a final concentration of 2000 μg/mL potassium in all solutions, including the blank.
Sample Preparation

Dissolve 1.000 g of sample in 10 mL hydrochloric acid in a covered beaker. Oxidize with 2 mL of 100 volume (30% w/v) hydrogen peroxide. Boil to destroy excess peroxide. Cool, transfer to a 100 mL volumetric flask and make up to volume with distilled water.

For analysis, take 10 mL of the prepared solution and add 2 mL of a solution containing 100 g/L potassium. Dilute to 100 mL with distilled water.

For 4.7% Al, the dilute solution will contain approximately 45 μg/mL Al.

Composite Standard Preparation

Prepare a range of composite standards containing a series of concentrations of Al, Cd, Cu, Fe, Mg, Pb in a pure zinc matrix. The solutions are prepared according to the schedules given in Tables 1 and 2.

Basic Matrix

Dissolve replicate 1.000 g lots of pure zinc in 10 mL hydrochloric acid. Oxidize with 2 mL of 100 volume (30% w/v) hydrogen peroxide. Boil to destroy excess peroxide. Cool and add aliquots of individual element solutions to give a range of standard concentrations in a final volume of 100 mL.

Element Addition Solutions

Refer to the individual element standard conditions for the preparation of standard stock solutions.

Prepare addition solutions at concentrations given in Table 1. Add aliquots of the addition solutions to the basic matrix above. Make up to 100 mL to give the range of standards in Table 2.

For example:

<table>
<thead>
<tr>
<th>Element</th>
<th>Concentration (μg/mL)</th>
<th>Aliquots (mL)</th>

Aluminium Addition Solutions

Prepare a stock solutions containing 10000 μg/mL Al as described under aluminium standard conditions, i.e.

‘Dissolve 1.000 g of aluminium wire in 20 mL hydrochloric acid with the addition of a trace of a mercury salt to catalyze the reaction. Dilute to 100 mL to give 10000 μg/mL Al.’

Prepare five composite standard solutions as specified in Table 2 using the basic matrix and the element addition solutions specified in Table 1. Thus for the aluminium addition, no aluminium stock solution is added to ‘S1’, 2 mL of aluminium solution is added to ‘S2’, 4 mL of aluminium solution is added to ‘S3’ and so on.

Now add element addition solutions for the other elements specified in Table 1 using appropriate aliquots of the element stock solutions. Finally, make up each of the five composite standards to 100 mL with distilled water.
For the determination of aluminium:

Take 10 mL of each of the composite standards and add 2 mL of a solution containing 100 g/L potassium. Dilute to 100 mL with distilled water.

The dilute composite standards will contain 0, 20, 40, 60, 80 μg/mL Al with 2000 μg/mL potassium added.

Cd (Cadmium)

Range

0.0003–0.0006% Cd

Interferences

A range of composite standards, prepared in a pure zinc matrix, is used to compensate for the large excess of zinc in the sample.

Sample Preparation

Refer to aluminium in zinc alloy. Use the undiluted solution; for 0.0005% Cd, the solution concentration will be approximately 0.05 μg/mL Cd.

Standard Preparation

Refer to aluminium in zinc alloy. The composite standards will contain 0, 0.03, 0.04, 0.05, 0.06 μg/mL Cd.

Cu (Copper)

Range

0.25–2.5% Cu

Interferences

A range of composite standards, prepared in a pure zinc matrix, is used to compensate for the large excess of zinc in the sample.

A nitrous oxide-acetylene flame is used to minimize the effect of high Zn/Cu ratios which tend to depress the absorbance.

Sample Preparation

Refer to aluminium in zinc alloy. Use the dilute solution; for 0.95% Cu, the solution concentration will be approximately 10 μg/mL Cu.

Mg (Magnesium)

Range

0.002–0.05% Mg

Interferences

A range of composite standards, prepared in a pure zinc matrix, is used to compensate for the large excess of zinc in the sample.

A nitrous oxide-acetylene flame is used to overcome interference from the sample matrix.

Sample Preparation

Refer to aluminium in zinc alloy. Use the dilute solution; for 0.045% Mg, the solution concentration will be approximately 0.5 μg/mL Mg.

Standard Preparation

Refer to aluminium in zinc alloy. Use the dilute range of composite standards. The dilute composite standards will contain 0.05, 0.1, 0.25, 0.5 μg/mL Mg.
Methodology

Pb (Lead)

Range
0.002–0.006% Pb

Interferences

A range of composite standards, prepared in a pure zinc matrix, is used to compensate for the large excess of zinc in the sample.

At the 217.0 nm wavelength, non-atomic species in the air-acetylene flame absorb strongly. Use a background corrector to check for the presence of non-atomic absorption.

Sample Preparation

Refer to aluminium in zinc alloy.

Use the undiluted solution; for 0.003% Pb, the solution concentration will be approximately 0.3 µg/mL Pb.

Standard Preparation

Refer to aluminium in zinc alloy.

The composite standards will contain 0, 0.2, 0.3, 0.4, 0.6 µg/mL Pb.
**Methodology**

**Petroleum**

**Gasoline**

**Pb (Lead)**

**Reference**

This method is adapted from:

**Sample Preparation**

Dilute 1.00 mL of gasoline to 50 mL with a solution containing 5 mg iodine per 50 mL methyl isobutyl ketone.

**Standard Preparation**

Dilute a tetra methyl lead standard with the iodine-methyl isobutyl ketone solution to give standards containing 0.02, 0.04, 0.06 g/gallon Pb. These standards correspond to 1.0, 2.0, 3.0 g/gallon Pb in the undiluted gasoline.

**Lubricating Oils**

**NOTE**

The adjustable nebulizer should be used with organic solvents to reduce the liquid uptake to about 2 mL/min.

**Al (Aluminium)**

**Range**

1–10 μg/g Al

**Sample Preparation**

Dissolve 10.00 g oil in methyl isobutyl ketone and dilute to 100 mL with the same solvent (Note 1 following).

For 1 μg/g Al, the solution concentration will be approximately 0.1 μg/mL Al.

**Notes:**

1. Any suspended material present in the sample is filtered off and analyzed separately by ashing and solvent extraction.
2. The method of standard additions is used. Standards are obtained by adding aliquots of known concentration to replicate sample solutions prior to making up to volume.

**Standard Preparation**

Prepare a 10 μg/mL Al solution using either:

- an organometallic compound of the organic sulfonate type (e.g., CONOSTAN®)
- aluminium cyclohexane butyrate.

* Registered trade mark of Continental Oil Company.

Prepare addition standards containing 0.0.1, 1 μg/mL Al by pipetting aliquots of the 10 μg/mL Al solution into replicate samples solutions prior to diluting to 100 mL with methyl isobutyl ketone.

**B (Boron)**

**Typical Analysis**

B 0.2% Zn 2%

**Sample Preparation**

Weigh duplicate 1.0 g samples of oil into 25 mL volumetric flasks and make up to volume with kerosine. Ensure that the oil and kerosine are thoroughly mixed.

**Standard Preparation**

Dissolve 4.16 g of menthyl borate (tri-dl-methylmenthyl borate) in xylene, disperse into a mixture of 4% paraffin oil and kerosine, and dilute quantitatively to 100 mL. This gives a solution of 1000 μg/mL B.

Prepare calibration standards of 100, 200 and 300 μg/mL B by diluting the standard with 4% paraffin oil in kerosine.

**Ba (Barium)**

**Range**

1–5%

**Interferences**

Some problems have been encountered in the determination of barium as organometallic salts because of the different nature of the alkyl groups. The addition of iodine at a level of 20 mg/100 mL has been found to overcome this effect. A sodium organometallic salt is added to overcome ionization interference.
Methodology

References

Sample Preparation

Dissolve 0.500 g of oil in kerosine and dilute to 50 mL. Dilute 1 mL of this solution to 100 mL with an addition of 10 mL of 10000 μg/mL sodium organometallic salt and 20 mg of iodine.

For 5% Ba, the solution concentration will be approximately 5 μg/mL.

Standard Preparation

Refer to barium standard conditions.

Prepare calibration standards containing 0, 2.5, 5, 10 μg/mL Ba, using barium organometallic standard. The standard solutions must contain the same reagents and major matrix elements as the sample solutions at approximately the same concentration. For example, in the typical case above the standards would contain:

- Na: 1000 μg/mL
- Iodine: 20 mg

Fe (Iron)

Range

Suitable for levels down to 0.5 μg/g.

Interferences

The organic solvent in this method acts as a supplementary fuel in the flame. It is essential to maintain thermal and optical equilibrium in the flame by aspirating a solvent blank continuously between samples.

A slightly fuel rich air-acetylene or a nitrous oxide-acetylene flame should be used to overcome interference due to the different forms of iron present. i.e., wear particles and iron organometallic compounds.

Sample Preparation

Refer to aluminium in lubricating oil.

The sample solution should be prepared in duplicate, adding 1 mL of 100 μg/mL Fe standard solution to one sample to give an additional concentration of 1 μg/mL Fe.

For 0.5 μg/g Fe, the solution concentration will be approximately 0.05 μg/mL Fe.

Sn (Tin)

Range

Suitable for 20–100 μg/g Sn in oil.

Interferences

At 224.6 nm, non-atomic species may absorb strongly. Use a background corrector to check for the presence of non-atomic absorption.

Sample Preparation

Dissolve 2.500 g of oil in methyl isobutyl ketone and dilute to 25 mL with the same solvent. For 20 μg/g Sn, this is 2 μg/mL Sn in solution.

Standard Preparation

Dissolve 0.431 g of dibutyl tin-bis-(2-ethyl hexanoate), 23.2% Sn, in 5 mL xylene with heating. Dilute to 100 mL with xylene to give 1000 μg/mL Sn.

Prepare a solvent blank of 10% new oil in methyl isobutyl ketone, using the same type and grade of oil. Prepare 2, 4, 6, 8 μg/mL Sn standards by diluting the xylene solution with this solvent blank.
Pollution

Air

Al (Aluminium)

Typical values
- Non urban areas: 0.08 μg/m³
- Metropolitan residential: 0.2 μg/m³
- Industrial: 0.6 μg/m³

Sample Preparation
Refer to cadmium in air. For a sample with 0.6 μg/m³ Al and sampling rate of 1.5 m³/min, the solution will contain 25.8 μg/mL Al.

Cd (Cadmium)

Typical values
- Natural levels: up to 0.001 μg/m³
- High city averages: 0.065 μg/m³
- Near smelters or other sources of cadmium emission: 1.0 μg/m³

Sample Preparation
Draw air with a high volume sampler through a preconditioned* fiberglass filter at the rate of 1.5–2.0 m³/min.

*The fiberglass filter is preconditioned by flash firing in a muffle furnace at 400 °C for 20–30 minutes to destroy the organic binders.

When cooled down the filter is washed with 50% v/v nitric acid, dried and stored in a desiccator until required for use.

Collect the sample for a 24 hour period. Remove the filter from the sampler and place in a muffle furnace at 250 °C for one hour. Cool the filter down and place in a suitable flask with 100 mL of 50% v/v nitric acid. Heat the contents of the flask and maintain just below the boiling temperature for 45 minutes. Filter the extract through a prewashed Whatman 540 paper and repeat the nitric acid extraction by heating for 45 minutes. Combine the filtrate and washings and boil down to moist salts. Redissolve in nitric acid and dilute to 50 mL with distilled water.

For air with 0.01 μg/m³ Cd at a flow rate of 1.5 m³/min the solution will contain 0.43 μg/mL Cd.

Standard Preparation
Prepare calibration standards containing 0, 0.2, 0.5, 1, 2 μg/mL Cd. The standard solutions should contain nitric acid at the same concentration as in the sample solution. Other major elements should also be matched.

Cu (Copper)

Typical values
- Non urban area: 0.01 μg/m³
- Metropolitan residential: 0.06 μg/m³
- Industrial: 1.0 μg/m³

Sample Preparation
Refer to cadmium in air. For a sample with 0.1 μg/m³ Cu and sampling flow rate of 1.5 m³/min, the sample solution will contain 4.3 μg/mL Cu.

Standard Preparation
Prepare calibration standards containing 0, 1, 2, 5, 8 μg/mL Cu.

The concentration of nitric acid in the standard should be approximately the same as in the sample solution.

Fe (Iron)

Typical values
- Non urban area: 0.06 μg/m³
- Metropolitan residential: 0.18 μg/m³
- Industrial: 0.82 μg/m³
Methodology

Sample Preparation
Refer to cadmium in air. For a sample with 0.2 μg/m³ Fe and sampling flow rate of 1.5 m³/min, the sample solution will contain 8.6 μg/mL Fe.

Standard Preparation
Prepare calibration standards containing 0, 5, 10, 20, 50 μg/mL Fe.
Adjust concentration of nitric acid in the standards to match content in the sample solution.

Pb (Lead)
Sample Preparation
Refer to procedure recommended for cadmium in air. For air sample containing 0.2 μg/m³ Pb and sampling flow rate of 1.5 m³/min, the sample solution will contain 8.6 μg/mL Pb.

Standard Preparation
Prepare calibration standards containing 0, 2, 5, 10, 20 μg/mL Pb using dilute nitric acid of the same concentration as in the sample solution for dilution.

Natural Water
As (Arsenic)
Vapor Generation Technique
At low concentrations, this element can be determined by the vapor generation technique. Details of the appropriate procedures are given in the operation manual supplied with the Agilent vapor generation accessory. Refer also to Agilent Instruments At work No. AA-38.

Range
40–500 ng arsenic
i.e., 0.004–0.05 mg/L arsenic in a 10 mL sample.
The lower limit is highly dependent on the level of arsenic in the blank, i.e., the amount of arsenic contained in the reagents.

Interferences
At the 193.7 nm wavelength, non-atomic absorption due to molecular species will necessitate the use of background correction.
Chemical interferences can be encountered in the generation of arsine. Oxidizing agents can prevent the reaction entirely. Excess nitric acid in particular must be absent from the test solution. Metals such as copper, which form a precipitate with potassium iodide, cannot be tolerated in large excess.

Sample Preparation
No preparation is required.

Standard Preparation
Prepare calibration standards containing 0, 0.005, 0.01, 0.02, 0.03, 0.04, 0.05 μg/mL (mg/L) arsenic so that 10 mL aliquots will contain 0, 50, 100, 200, 300, 400, 500 ng arsenic.

Hg (Mercury)
Cold Vapor Technique
Essentially, the method depends on the reduction of available mercury in a reducible state (mainly Hg₂⁺) to the elemental state by reaction with stannous chloride.

\[ \text{Hg}^{2+} + \text{Sn}^{2+} \rightarrow \text{Hg} + \text{Sn}^{4+} \]

The mercury vapor is then purged into an absorption cell which is located in the light path of the spectrometer in place of the normal flame burner. The resultant absorbance peak is then measured. Refer also to Agilent Instruments At work No. AA-38.

Range
Up to 600 ng Hg
i.e., 0.012 mg/L Hg in a 50 mL sample.
Detection limit: 2 ng Hg (0.00004 mg/L in a 50 mL sample).

Interferences
Metallic ions which are reduced to the elemental state by stannous chloride will interfere if they amalgamate or form stable compounds with mercury. For example, gold, platinum, selenium and tellurium have been found to interfere at various concentrations as have iodide, bromide and thiosulfate. If interference is suspected, it can be checked by the standard additions method.
The use of background correction to correct for non-atomic absorption may be necessary.

Special Reagents

Stannous chloride solution 20%:
Add 40 g of A.R. stannous chloride to 200 mL concentrated hydrochloric acid. Boil gently in a covered beaker until dissolved. Add one piece of A.R. granulated tin and allow to cool. To ensure that the solution remains in the stannous state, it is necessary to add a granule of metallic tin periodically so that an excess is always present.

Potassium permanganate solution 2%:
Dissolve 2 g of A.R. potassium permanganate in 100 mL distilled water.

Potassium persulfate 5%:
Dissolve 5 g of A.R. potassium persulfate in 100 mL distilled water.

Hydroxylamine hydrochloride 3%:
Dissolve 3 g of A.R. hydroxylamine hydrochloride in 100 mL distilled water.

Sample Preparation

Mercury may be present in water as free (ionic) mercury or as organically-bound mercury.

Free mercury is readily reduced by stannous chloride but the organically-bound mercury must be pre-digested so that the total mercury content can be measured.

Total mercury-pre-digestion
Take replicate 50 mL aliquots of sample. Add 10 mL 1:1 sulfuric acid and 1 mL of 2% potassium permanganate solution. Allow to stand for 15 minutes and then add 1 mL of 5% potassium persulfate. Heat the mixture to 95 °C on a water bath for about one hour. Cool and add 3% hydroxylamine solution until permanganate color is discharged.

Standard Preparation

Refer to mercury standard conditions.
Prepare calibration standards containing 0, 0.002, 0.004, 0.008 and 0.012 μg/mL (mg/L) mercury so that 50 mL aliquots will contain 0, 100, 200, 400, 600 ng mercury.

All solutions should have a final acid concentration of 10% nitric acid.

Se (Selenium)

Vapor Generation Technique

At low concentrations, this element can be determined by the vapor generation technique. Details of the appropriate procedures are given in the operation manual supplied with the Agilent vapor generation accessory.

In this method, any selenium(VI) in solution is reduced to selenium(IV) by the action of hot 50% hydrochloric acid.

Range

40–1000 ng selenium
i.e., 0.004–0.1 mg/L selenium in a 10 mL sample.

The lower limit is dependent on the amount of selenium contained in the reagent blank.

Interferences

At the 196.0 nm wavelength, non-atomic absorption due to molecular species may necessitate the use of background correction. Chemical interference can be encountered in the generation of hydrogen selenide. Oxidizing agents can prevent the reaction entirely. Excess nitric acid in particular must be absent from the test solution. Iodide ions must be avoided. Metals such as copper, which form a precipitate with potassium iodide, cannot be tolerated in large excess.

References

Sample Preparation

No preparation is required.
Methodology

Standard Preparation

Refer to selenium standard conditions.

Prepare calibration standards containing 0, 0.005, 0.01, 0.02, 0.04, 0.06, 0.08, 0.1 μg/mL (mg/L) selenium so that 10 mL aliquots will contain 0, 50, 100, 200, 400, 600, 800, 1000 ng selenium.

Sewage Effluent

Cr (Chromium)

Range

0.1–1.0 μg/mL Cr

Interferences

High levels of iron, cobalt and chloride can cause interference unless optimum flame conditions are used.

Sample Preparation

Samples must be collected in acid washed containers. Acidify the sample by addition of hydrochloric acid to level of 1%.

Standard Preparation

Refer to chromium standard conditions.

Prepare calibration standards containing 0, 0.1, 0.5 and 1.0 μg/mL Cr in 1% hydrochloric acid.
